

The Navy SEAL Physical Fitness Guide

Edited by Patricia A. Deuster, Ph.D., M.P.H.

The Navy SEAL Physical Fitness Guide

Edited by Patricia A. Deuster, Ph.D., M.P.H.

Department of Military and Emergency Medicine
Uniformed Services University of the Health Sciences
August 1997

Acknowledgments

The authors would like to recognize the invaluable contributions to the development of this guide by the following individuals. CAPT Kenneth Long participated in both panel reviews and provided useful suggestions and comments. His meticulous work was greatly appreciated by all. CAPT Peter Toennies reviewed and provided substantive comments about the chapter “Swimming for Fitness”. Mr. Jeremy Levine and Ms. Brandi Schoeber provided information about strength training.

Importantly, we were extremely fortunate to receive valuable input from several SEALs throughout the development of this guide. ENS Frances Franky and BM1 George Vernia participated in the first panel review and their suggestions were incorporated in the second draft of the manual. BM1 Vernia helped organize and participated in the second and final panel review. Other SEAL panel reviewers included CW03 John Shellnut, Master Chief Bob Bender, LCDR Pat Butler, and BMCS Duane Noel. Each one of these SEALs provided suggestions and practical recommendations which were instrumental in the finalization of the “*The Navy SEAL Physical Fitness Guide*”.

About the Authors

CAPT Frank K. Butler, Jr., M.D., developed the chapter “SEAL Mission-Related Activities”. He is currently the Biomedical Research Director for the Naval Special Warfare Command, Chairman of the U.S. Special Operations Command Biomedical Initiatives Steering Committee, and a Staff Ophthalmologist at the Naval Hospital, Pensacola, Florida. He obtained his undergraduate degree from Georgia Institute of Technology in 1971, with high honors. His medical degree is from Medical College of Georgia, 1980. Dr. Butler’s Family Practice Internship was at the Navy Regional Medical Center, Jacksonville, Florida (1980-1981) and his Ophthalmology Residency was at the National Naval Medical Center, Bethesda, MD. where he was Chief Resident (1988-1989). He completed his Undersea Medical Officer Training from the Undersea Medical Institute, Groton, Ct., 1981. CAPT Butler has been a platoon Commander for Underwater Demolition Team TWELVE and SEAL Team ONE, and a Diving Medical Research Officer at the Navy Experimental Diving Unit. He has published extensively and been a frequent guest lecturer on the subject of closed-circuit diving and Special Warfare.

CAPT John S. Hughes, M.D., developed the chapter “Swimming for Fitness” and contributed to “Other Training-Related Issues”. He is a Navy Reserve Undersea Medical Officer who resides near Littleton, Colorado. A graduate of the University of Colorado School of Medicine, Dr. Hughes has a Naval Reserve assignment to NAVSEA in Crystal City, Virginia, where he is assigned to the Supervisor of Diving and Salvage. Dr. Hughes has been involved with Navy diving medicine since 1981. He is Board Certified in Occupational Medicine and his civilian medical practice in Colorado and Wyoming involves operation of clinics and health facilities covering a wide range of high risk industries including commercial diving.

Special qualifications allow Dr. Hughes to participate in the development of the Navy SEAL Physical Fitness Guide. He swam freestyle in the NCAA Championships and won the 1976 Big 8 Conference Championship in the 1650 yd freestyle for the University of Colorado and has remained active as a competitive swimmer. As a mountaineer and cross country skier he has organized and participated in numerous climbs, including two on

Denali and Denali North Peak in Alaska. His instrumental work with the SEAL team in developing a winter warfare program during 1982 led him to participate as a staff member of the SEAL winter warfare Greenland operation in 1983. For this involvement, Dr. Hughes received a letter of appreciation from the CO of SEAL Team TWO, CDR Rick Woolard. With the theme of Dr. Hughes' career being medical support of high risk military and industrial operations, he feels that work for the SEALs is at the head of the list.

CAPT Joseph Moore, M.D., developed the chapter “Training and Sports-Related Injuries. He completed his undergraduate degree in 1978, and medical degree in 1982 from the University of Virginia after which he was commissioned as a Lieutenant in the Naval Medical Corps. CDR Moore completed his internship at Naval Medical Center, Oakland, California, in June 1983, and received orders to the 1st Marine Division, Camp Pendleton, California. He served as Battalion Surgeon, 2nd Battalion, 9th Marines from July 1983 to October 1985, deploying to Okinawa, Korea and Panama. He also served as 5th Marines Regimental Surgeon during this time period. He completed a Family Practice residency at the Naval Hospital, Camp Pendleton in 1987, followed by a tour as Senior Medical Officer on the island of La Maddalena, Italy. CDR Moore was the first Navy physician selected for a primary care Sports Medicine fellowship, and trained at the San Diego Sports Medicine Center and San Diego State University from December 1989 through January 1991.

CDR Moore is currently the Department Head and Fellowship Director for the Navy's Sports Medicine program at the Naval Hospital and Marine Corps Base, Camp Pendleton. In addition to his duties as Specialty Leader to the Surgeon General, Dr. Moore serves as chairman of the Sports Medicine Advisory Panel to the U.S. Naval Special Warfare Command, Coronado, and advisor to Marine Corps Combat Development Command, Quantico. His work with the civilian community has earned him an appointment by the Governor of California to the Governor's Council on Physical Fitness and Sports. He also holds an appointment to the United States Olympic Committee Team Physician Development Program, Colorado Springs, CO. He is co-chairman of the American Academy of Family Physicians' Review Course for Sports Medicine.

CDR Brad L. Bennett, Ph.D., developed the Chapter “Load Bearing” and he has written a technical report “Load Carriage: Are You Preparing Correctly? Naval Medical Research Institute, Technical Memo 96-71, 1991”. He is a research physiologist currently assigned to the Department of Military and Emergency Medicine, School of Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD. He serves as an Assistant Professor and Director of the Basic Sciences Division. He is a graduate of Wilderness Medicine, and Tactical Emergency Medical Technician courses, and is a department faculty member in the Counter Narcotics Tactical Operations Medical Support (CONTOMS) course as sponsored by the Department of Defense. He earned a Bachelor and Master Degrees in Exercise Science from San Diego State University and a Ph.D. in Kinesiology from the University of Maryland.

He has completed the Navy's diving medicine course and became designated as a Navy Medical Department Deep Sea Diving Officer. He has conducted biomedical research on the impact of environmental stressors on human performance of Navy Special

Warfare (SEAL) personnel, U.S. Marine Corps personnel, and Navy damage control personnel. Dr. Bennett currently serves as the Special Advisor to Navy Surgeon General for Physiology.

Dr. Bennett has enjoyed long distance running (10k, half marathons and marathons) for over twenty years. Other hobbies of interest are hiking, kayaking, camping, weight training, target and skeet shooting.

LCDR Lisa Thorson, M.D., wrote the Chapters on Flexibility, Calisthenics and Plyometrics. She earned her B.S. in psychology at the University of Oklahoma in Norman, Oklahoma, and her M.D. from the University of Oklahoma School of Medicine. She has completed the Undersea Medical Officer course and had a tour of duty at the Diver Second Class Training Department, Naval Amphibious School, Naval Amphibious Base, Coronado. LCDR Thorson has been involved with the Exercise-Related Injury Program, and all aspects of injury prevention for the Special Operations Community. Projects have included the development of injury tracking software used by the Special Operations community. She also organized the first Naval Special Warfare Sports Medicine conference held May 1994. Recommendations from this conference are documented in Naval Health Research Center Technical Document Number 95-4D, "Naval Special Warfare Sports Medicine Conference Proceedings," and Number 95-5D, "Expert Panel Review of the Naval Special Warfare Calisthenics Sports Medicine Conference Summary."

Currently she is in Residency training in Preventive Medicine at the Uniformed Services University of the Health Sciences, Bethesda, Maryland, where her work documenting injuries in the Special Operations community will continue. She has 13 years of ballet training, has taught and competed in aerobic dance competitions, and spends her time weight-training.

Patricia Deuster, Ph.D., M.P.H., the editor of this guide, wrote "Cardio-respiratory Conditioning" and "Strength Training" and contributed to "Other Training-Related Issues". She compiled the group's recommendations and wrote the chapter "Physical Fitness and Training Recommendations". She is an Associate Professor and Director of the Human Performance Laboratory in the Department of Military and Emergency Medicine at the Uniformed Services University of the Health Sciences, School of Medicine in Bethesda, Maryland. She has an undergraduate degree in Mathematics, and graduate degrees in Physical Education (M.A.), Nutritional Sciences (Ph.D.), and Public Health (M.P.H.). Her credentials for editing this book are many. She has been conducting research in the area of sports nutrition and exercise physiology for over 14 years. Dr. Deuster has published numerous papers on the nutritional needs of U.S. Navy SEALs, and has given many sports nutrition seminars to high school, college, and professional athletes, recreational athletes, SWAT teams, dietitians, and other health professionals. She is also an athlete herself. She was a tennis professional for five years and has competed in several triathlons and over 20 marathons; her best marathon time was a 2:48 in the Boston Marathon. Dr. Deuster was a nationally ranked runner for several years and a qualifier for the First Women's Olympic Marathon Trials. She is an avid sportswoman and a former skydiver who has logged in over 100 jumps.

Anita Singh, Ph.D., wrote “Overview of Physical Fitness” and “Running for Fitness” and assisted Dr. Deuster with the editing of this guide. She is an Assistant Professor in the Department of Military and Emergency Medicine at the Uniformed Services University of the Health Sciences, Bethesda, Maryland. Dr. Singh has a Ph.D. in Nutrition from the University of Maryland, and she has been working in the area of Sports Nutrition and Exercise Physiology for over 10 years. In addition to looking at nutritional needs of U.S. Navy SEAL trainees, she has studied marathoners, ultramarathoners, and recreational athletes. She has presented her research work at various national and international meetings. Dr. Singh has published extensively in scientific journals and she co-authored “*The Navy SEAL Nutrition Guide*”. She runs and plays tennis.

CDR Kevin C. Walters, M.D., developed the chapter “Training for Specific Environments”. He is a Diving Medical Officer at the Naval Special Warfare Center in Coronado, CA. Dr. Walters enlisted in the Navy in 1974, and graduated from BUD/S in 1976 (class 87) and served five and a half years at SEAL Team ONE. He left active duty in 1983 to return to college and graduate school. He received his M.D. degree in 1993 from the Uniformed Services University of the Health and subsequently completed a Transitional Internship at the Naval Medical Center, San Diego, CA.

CAPT Steve Giebner, M.D., contributed to the chapter “Harmful Substances that Affect Performance”. He is currently the Force Medical Officer for Commander, Naval Special Warfare Command. His association with the Naval Special Warfare community goes back to 1982 when he took his first operational assignment as the Diving Medical Officer for the Naval Special Warfare Training Department of the Naval Amphibious School, Coronado. He is also plank owner at Naval Special Warfare Center as the first Medical Officer assigned to that command.

Dr. Giebner specialized in Sport and Exercise Preventive Medicine and Health Promotion, having earned the Master of Public Health degree in the Preventive Medicine residency at the University of California at San Diego and San Diego State University. He has long been an active proponent of Sports Medicine in the Navy, and especially within Naval Special Warfare. His long association with Navy SEALs and his professional training uniquely qualify him to contribute to this manual.

In addition to recreational tennis, golf, and in-line skating, Dr. Giebner has consistently participated in command endorsed physical training programs throughout his Naval career. This year marks his first entry in the San Diego Marathon and a Superfrog Triathlon relay team.

HMC Denise E. Becker, USNR, developed “Appendix A - Weight Lifting Techniques” and assisted in the editing of this guide. She has a B.S. in Occupational Education and is pursuing a Masters degree in Exercise Physiology. She has served as the Training Chief and is currently assigned to Assault Craft Unit-4 Det 1 as Division Officer and the Medical Department Representative. An avid sportswoman, she has participated in several half marathons, 10 and 5K races, and triathlons. She competed in the Tidewater All-Navy Tennis Tournament. Chief Becker is married to a SEAL, Al Becker, LCDR, USN-RET and they have five children. The whole family has participated in the UDT/ SEAL Reunion Family Fun Run the past 10 years.

An Introduction by RADM Raymond C. Smith

Membership in the Naval Special Warfare (NSW) community requires an extraordinarily high level of total body physical fitness. A combination of muscular strength, flexibility and cardiovascular fitness is essential to carry out assigned missions.

To train most effectively for these physically demanding tasks, SEALs and others within the NSW community need clear, concise, and authoritative guidance on physical fitness training regimens. This manual, *The Naval Special Warfare Physical Fitness Guide*, has been written to meet this need.

The authors of this comprehensive guide, physicians and physiologists, were chosen because of their special qualifications in the area of physical fitness and their knowledge of the NSW and SEAL community. Their expertise ensured the guide would be written with the unique requirements of the NSW community in mind, and that our goal of expanding the individual Navy SEAL's knowledge of attaining and retaining a high level of fitness would be achieved.

I commend *The Naval Special Warfare Physical Fitness Guide* as a superb source of information. Following the advice in this guide will enable SEALs and other members of the NSW community to prepare for the physically demanding missions to which they are assigned in the future.

Introduction

The Navy SEAL Physical Fitness Guide has been prepared for the SEAL community with several goals in mind. Our objective is to provide you, the operator, with information to help:

- ◆ Enhance the physical abilities required to perform Special Operations mission-related physical tasks;
- ◆ Promote long-term cardiovascular health and physical fitness;
- ◆ Prevent injuries and accelerate return to duty;
- ◆ Maintain physical readiness under deployed or embarked environments.

If this guide is able to achieve those goals, it will be a major success. Being a SEAL is a tough job and requires enormous physical strength and stamina. Injuries, both chronic and acute are occupational hazards, but there are training measures and precautions that can be used to decrease the incidence of these injuries. Understanding the basics of physical fitness can go a long way to achieving these goals.

Physical fitness is typically considered a set of characteristics that people gain through various physical efforts. In fact, physical fitness consists of a variety of **measurable** components, some of which are skill-related and others which are health-related. The components of physical fitness are presented in 0-1

Table 0-1. Skill- and Health-Related Components of Physical Fitness

Skill-Related	Health-Related
Agility	Cardiorespiratory endurance
Balance	Muscular endurance
Coordination	Muscular strength
Speed	Body composition
Power	Flexibility
Reaction time	

Definitions for each of these components/terms are provided in Chapter 1: Overview of Physical Fitness; all are extremely important in SEAL training. Because these components are measurable, it is clear that there are levels of physical fitness which can range from very low to exceptionally high. Moreover, a wide range may exist across particular components within an individual. For example, a person may have exceptional cardiorespiratory endurance, but have very poor flexibility. Thus, a high level in one component does not translate into high physical fitness. A highly fit person should achieve a high level in each of the health-related components for protection of health. However, for SEAL training, components of both skill and health-related groups are requisite. This guide should help you achieve a more favorable balance among the various components, and serve as a resource for you in the future.

Chapter 1

Overview of Physical Fitness

This chapter will introduce terms and definitions commonly used to measure or define fitness levels, and other terms associated with athletic training. Terms such as aerobic and anaerobic will be appearing throughout this fitness guide and various training techniques to optimize fitness will be discussed in greater detail in subsequent chapters. We suggest that you take some time to familiarize yourself with the terms and concepts in this chapter as this will greatly enhance your ability to apply the information provided in the remaining chapters.

Exercise Physiology

Exercise physiology is a branch of science which studies how the body responds and adapts physically to exercise training or to an acute bout of physical exertion. Such information is used for designing physical education, fitness and athletic programs. Physical fitness includes cardiopulmonary endurance, body composition, muscular strength and endurance, and flexibility.

Definitions and Terminology

Following are some commonly used exercise physiology terms and their definitions. You will come across many of these terms in subsequent chapters.

Aerobic: A process of producing energy that requires oxygen.

Aerobic Capacity: Total or maximal amount of aerobic work that can be done.

Aerobic Metabolism: Most of the energy needed to support exercise that goes beyond 3 minutes is provided by aerobic or oxidative energy metabolism. In other words oxygen is required to produce energy.

Agility: Ability to change physical position with speed and accuracy.

Anaerobic: A process of producing energy that does not require the presence of oxygen.

Anaerobic Capacity: Total or maximal amount of anaerobic work that can be done.

Anaerobic Glycolysis: A process of breaking down glycogen stores without oxygen; lactate (lactic acid) is the by-product of this process.

Anaerobic Metabolism: A type of energy metabolism that does not require oxygen.

Anaerobic Threshold: Transition point when aerobic metabolism can no longer meet the energetic demands, and energy from sources independent of oxygen are required. This is also the work rate at which blood lactate concentrations start to increase during graded exercise.

Adenosine Triphosphate (ATP): Energy released from food is stored in the muscle in the form of ATP. When ATP is broken down energy is released.

Balance: Ability to maintain equilibrium when stationary or while moving.

Cardiorespiratory Fitness: Ability of the heart, lung and blood vessels to transport oxygen and to remove waste products from the exercising muscle.

Concentric Contraction: Shortening of the muscle as it develops tension. This type of exercise is sometimes known as “positive exercise”.

Coordination: Ability to use the senses, such as sight, along with the functioning of a set of muscle groups to complete an activity accurately. For example: hand-eye coordination during rifle shooting.

Dynamic Exercise: Alternate contraction and relaxation of a skeletal muscle or muscles causing partial or complete range of movement through a joint.

Eccentric Contraction: Involves the lengthening of a muscle as it develops tension and is also known as “negative exercise”. Eccentric contractions are used when resisting gravity as is the case in walking down hill or down stairs.

Electrocardiogram (ECG): A tracing that shows the electrical activity of the heart.

Ergometer: Instrument used to measure work and power.

Ergometry: Measurement of work and power during exercise.

Exercise: Planned, structured, and repetitive movements performed to improve or maintain components of physical fitness. The components include cardiorespiratory fitness, muscle strength and endurance, flexibility and body composition (see Introduction).

Fartlek Training: An unstructured type of interval training for speed-work.

Flexibility: Controlled range of motion of a specific joint. The range is a function of elasticity of the tendons, ligaments, and surrounding soft tissue. Control is a function of strength at each degree of motion, especially at the end ranges.

Glycogen: A form of carbohydrates that is stored in the liver and in muscles for energy.

Glycolysis: Breaking down of simple sugars into simpler compounds (chiefly pyruvate and lactate) for energy. This process is anaerobic.

Glycolytic: Pertaining to or promoting glycolysis.

Heart Rate: Number of heart beats per minute.

Interval Training: Very intense exercise bouts are alternated with rest or periods of low intensity exercise. Exercise during intervals is typically anaerobic.

Isokinetic: Contraction of a muscle or muscle group which results in joint movement at a constant angular velocity. For example: the arm stroke during free style swimming.

Isometric (Static): Muscle contracts without shortening or lengthening such that tension is developed but no muscular work is performed; energy is lost as heat. There is no joint movement during this type of exercise.

Isotonic (Dynamic): Muscle contracts and maintains constant tension by lengthening or shortening.

Lactic Acid (lactate): A by-product of anaerobic metabolism.

Ligament: A band of fibrous tissue that connects bone to bone or bone to cartilage so as to strengthen joints.

Maximal Oxygen Uptake (VO_{2max}): A measure of aerobic fitness: the maximal rate of oxygen uptake, and therefore aerobic energy utilization during exercise. Typically expressed as liters per minute or milliliters per kilogram (kg) body weight per minute (ml/min/kg).

MET (Metabolic Equivalent Unit): A unit used to estimate the metabolic cost of physical activity. One MET is the energy used by an individual at rest. This is equivalent to 3.5 ml of oxygen consumed per kg body weight per minute.

Metabolism: Physical and chemical processes that maintain life.

Minute Ventilation: Volume of air breathed per minute.

Muscular Endurance: Ability of a muscle or muscle group to contract at a submaximal force, usually against 50 to 60% of maximal resistance, over a period of time. Measured as the number of repetitions completed.

Muscular Strength: Maximal force or tension generated by a muscle or muscle group.

Myoglobin: An iron containing muscle protein that is responsible for the reddish color of various muscle fiber types.

Physical Activity: Movement by skeletal muscles that results in energy expenditure.

Physical Fitness: Ability to perform physical activity.

Plyometrics: Also known as explosive jump training. Muscles are rapidly stretched prior to contraction. Examples include standing jumps, multiple jumps, etc.

Power: Ability of a muscle to quickly generate force over a very short period of time. Examples include sprint starts, vertical jumps, kicks and throwing a punch.

Rating of Perceived Exertion (RPE): Measured using the Borg Category RPE Scale. As exercise intensity increases, the RPE increases and in general it is closely associated with physiological measures such as heart rate and oxygen consumption.

Reaction Time: Time taken between receiving a signal and reacting to it.

Respiratory Exchange Ratio: Ratio of carbon dioxide produced to oxygen consumed. An indication of the primary energy source used during exercise.

Speed: Ability to perform a movement in a short period of time.

Strength: Ability of a muscle to contract against resistance and provide control throughout the full range of motion.

Stroke Volume: Volume of blood pumped from the heart with each beat.

Tendon: A fibrous cord in which the fibers of a muscle end and by which the muscle is attached to a bone or other structure.

Tidal Volume: Volume of air moved during one breathing cycle while inhaling or exhaling.

Muscle Structure and Function

The three major types of muscle are:

- ◆ Cardiac muscle
- ◆ Skeletal muscle
- ◆ Smooth muscle

This discussion will be limited to skeletal muscles which, by converting chemical energy to mechanical energy, produce movement. We will present a description of the subtypes of skeletal muscles, including their characteristics and distribution. Although there may be many new subtypes of skeletal muscle fibers, generally skeletal muscle can be characterized into three basic types:

- ◆ Slow Twitch Oxidative (Type I)
- ◆ Fast Twitch Oxidative-Glycolytic (Type IIa)
- ◆ Fast Twitch Glycolytic (Type IIb)

Type I Muscle Fibers

Type I muscle fibers are involved in endurance activities. These fibers, also called **slow twitch fibers**, are noted for their ability to produce energy in the presence of oxygen. Thus, they are primarily aerobic. The main fuel source for this fiber is **fats (fatty acids)**, which allow the muscle to work at a steady rate with noticeable resistance to fatigue. Their color is typically quite red, a result of the high content of “myoglobin”, an iron-containing protein that stores and delivers oxygen. Slow twitch fibers are not noted for their speed, their anaerobic capacity, or their ability to contract at a fast rate repeatedly, but rather their indefatigability and aerobic capacity.

Type II Muscle Fibers

Type II fibers can be categorized into at least two types: Type IIa and Type IIb. These fibers are adapted for strength and power activities. The **Type IIa fiber** is a cross between a slow twitch and a fast twitch fiber in that it is both aerobic (oxidative) and anaerobic (glycolytic). Whereas, it is “faster” than the slow twitch fiber, it is not as well suited for endurance activities. Its color is also reddish, a result of the myoglobin content.

In contrast, the **Type IIb fiber** is truly a fast twitch fiber, with very high contraction speeds. These fibers are almost exclusively anaerobic and have minimal capacity for aerobic production of energy. They rely primarily on glycogen within the muscle for energy and are therefore very susceptible to fatigue. Their color is pale, and some consider it “white” because it lacks myoglobin. Type IIb fibers tend to accumulate lactate, which ultimately leads to rapid fatigue if the lactate is not removed.

It should be noted that each of the fiber types has different recruitment patterns, and typically the Type IIb fiber is only recruited for use during maximal effort. The other fibers contract during light as well as moderate activity. **Moreover, physical training can lead to changes in the characteristics of the fibers.** Thus, endurance training would lead to changes in the Type IIa fiber such that they take on more characteristics of the Type I, or slow twitch fiber. Table 1-1 presents the distinguishing characteristics of the various fiber types.

Table 1-1. Distinguishing Characteristics of Major Muscle Fiber Types

Fiber Characteristic	Slow Twitch	Type II a Fast Twitch	Type II b Fast Twitch
Aerobic Capacity	High	Moderate/High	Low
Anaerobic Capacity	Low	High	High
Contraction Speed	Slow	Fast	Fast
Fatigue Resistance	High	Moderate/High	Low
Myoglobin Content	High	High	Low
Glycogen Content	Low	Moderate	High
Color	Red	Reddish-white	White

Distribution of Fiber Types

The amount of Type I and Type II muscle fibers in an individual is genetically pre-determined, and all normal skeletal muscle contains all fiber types. However, the proportion or distribution of these fiber types within and across individuals differs. Moreover, within an individual, the distribution of fibers in various muscles can vary widely. **Physical training may transform muscle fiber type, and the metabolic capacity of both type I and type II muscle fibers can be modified by endurance and power training.** It should be noted that performance depends not only on your fiber type composition, but also on the interplay between a variety of factors such as training, and diet, etc. Figure 1-1 represents the average percentage of slow twitch (Type I) fibers found in various subgroups of the population. As can be seen, persons whose activities are primarily endurance-related have a higher proportion of Type I fibers as compared to sprinters or wrestlers. Also in Figure 1-1 are the maximal aerobic capacities of these groups: the greater the proportion of Type I fibers, the higher the maximal aerobic capacity. Note the wide variability in the group of “recreational athletes”. Specific types of training can induce changes in muscle fiber composition and characteristics.

Figure 1-1. Muscle Fiber Composition and Maximal Oxygen Uptake Values for Various Athletes by Sport

Principles of Physical Training

The goal of any training program is to improve performance. You are unique in terms of your excellent physical condition and your dedication to further enhancing your fitness. The four principles that apply to all physical training programs are discussed below.

Overload

According to this principle, exercise must be done at a higher level than usual to bring about various training adaptations. Once the body has adapted to the higher level of exercise it will function more effectively and efficiently. **The overload can be obtained by manipulating various combinations of exercise frequency, intensity, duration and type of exercise.** Increasing intensity, duration and frequency can be helpful for running, cycling or swimming, and increasing resistance and repetitions can improve strength training.

Specificity of Training

This principle refers to the training-induced adaptations in metabolic and physiologic systems which are specific to the type of exercise. For example, running will increase physical fitness but it will not increase swimming performance and vice versa. Thus, it is important to train muscles involved in a specific type of exercise to realize greater performance benefits.

Individual Differences

Responses to a particular training program can vary from one individual to another. According to this principle, exercise programs should be individualized to meet the training requirements and physical capacity of each person.

Detraining

Regular exercise is necessary to maintain fitness. Beneficial effects of exercise are gradually lost or reversed after a few weeks off from training. This deconditioning or detraining effect will be discussed later in this chapter.

Because of the nature of your missions it is imperative that you develop all aspects of physical fitness: strength, speed, flexibility, and endurance. Therefore, it is important for you to consider your training in terms of the FITT principle.

FITT = Frequency, Intensity, Time & Type

All four aspects of the **FITT** principle must be included to achieve the most benefit from your training program. Number and intensity of workouts is important as is the time spent exercising and cross training (see Chapter 3). Information on how to determine your training intensity is provided next.

Determining Your Training Heart Rate

When reading the training methods presented in this chapter and throughout this guide, you will come across references to exercise intensity. **Intensity is the rate at which exercise is performed.** If you work out in a gym you may have used an exercise machine that monitors exercise intensity. A quick and easy method for measuring the intensity of your workout is by measuring your heart rate and checking to see if you are within your target training zone (see below).

Measure your heart rate by taking your pulse at the carotid artery (neck) or the radial artery (wrist) for 15 seconds; multiply this value by four to get your heart rate in beats per minute. Compare this heart rate value to your target training intensity. If your heart rate is too low, increase the intensity of your workout. If it is too high, reduce the intensity slightly.

Your target training heart rate can be calculated as follows:

To maintain aerobic conditioning, exercise should be performed at a heart rate between 70% and 90% of your **maximal heart rate (Max HR)**.

Remember, this is only an estimate of your maximal heart rate.

Depending on your particular “physiology” and physical conditioning, your Max HR could be higher than what you derive from this equation. However, this is the way it is routinely estimated.

$$\text{Max HR in beats per minute} = 220 - \text{your age (years)}$$

To calculate 70% and 90% of your Max HR, multiply Max HR by 0.70 and 0.90, respectively. This is your target training intensity zone or the range within which your heart rate should be while working out. Figure 1-2 presents an example of how to calculate your desired training heart rate by this method.

Figure 1-2. An Example for Determining Your Target Training Heart Rate

Determining Your Target Heart Rate

A SEAL is 22 years old

Max HR = $220 - 22 = 198$ bpm

Lower Target HR = $0.7 \times 198 = 139$ bpm

Upper Target HR = $0.9 \times 198 = 178$ bpm

Calculate your target training heart rate zone using the formula provided above or use the chart shown in Figure 1-3. It is important to note that maximal heart rates tend to be lower during swimming and arm exercises. For these activities you should subtract 13 from your maximal heart rate to before obtaining your training heart rate. An example of this is shown in Figure 1-4.

Figure 1-3. Target Training Heart Rate Zone

Figure 1-4. An Example for Determining Your Target Training Heart Rate for Swimming

A 22 year old SEAL wants to swim at 70% of Max HR

Then his Max HR = $220 - 22 = 198 - 13 = 185$ bpm

70% of Max HR = $0.7 \times 185 = 130$ bpm

Energy Systems Used by Exercising Muscle

Before describing the methods used for physical training, it is important to understand the three systems that provide energy to the exercising muscle. All three systems are important. Depending on the activity, there may be a greater reliance on one system over the others.

ATP-CP System for Speed Work

Adenosine triphosphate (ATP) is the immediate source of energy within all cells of our body for activities such as sprinting. There are small stores of ATP within skeletal muscle, and these energy stores provide immediate energy to sustain physical activities for a short time. Once the ATP is used, it breaks down into adenosine diphosphate (ADP). For regeneration of ADP into ATP for more energy, creatine phosphate (CP) is needed. It is the CP that regenerates the ATP. Without CP, ATP could provide energy for only a few seconds. With CP, the ATP-PC system can provide energy for about 30 seconds before other energy systems must take over. Thus, this ATP-CP system, sometimes referred to as the phosphate pool or reservoir, provides immediate anaerobic energy for muscle contraction.

ATP → ADP + Phosphate + Energy

ADP + CP → ATP + Creatine

Lactic Acid and ATP-CP System for Anaerobic Work

This is a transitional system. When all-out exercise continues beyond 30 seconds, the only way to continue providing ATP to the exercising muscle is by using sugar (glucose) in the muscle. Sugar in the muscle is obtained from glycogen, and the process of breaking down sugar for energy is called glycolysis. However, in the process of generating ATP from glucose, lactic acid (also known as lactate) is formed. Normally there is only a small amount of lactate in blood and muscle. When lactate begins to accumulate in muscle and then blood, you will begin to experience muscular fatigue, unless it is cleared by the body. Lactate is cleared from the muscle if the intensity of the exercise is moderate. This happens because after a few minutes the aerobic or oxygen system, which supplies energy for sustained work, kicks in. If an all out effort is sustained, fatigue is inevitable within three to five minutes.

Oxygen System for Aerobic Energy

The oxygen, or aerobic, system provides energy to support long-term steady state exercise, such as long distance running or swimming. **Muscles can use both glucose and fatty acids for energy.** These fuel sources can be taken from the circulating blood and from stores within the muscle. Glucose is stored as glycogen and fatty acids are stored as “triglycerides” in the muscle. When long duration activities are performed at a slow pace more “fat” in the form of fatty acids is used for energy than muscle glycogen.

During many types of exercise, all three energy transfer systems are used at various times. The amount that each system contributes to energy metabolism is related to the duration, intensity and type of activity. In general, high intensity, short duration exercises rely mainly on anaerobic energy. Other examples specific to various activities are provided in Table 1-2.

Table 1-2. Percentage Contributed by Each Energy System to Overall Energy Needs of Various Activities

Physical Activity	ATP-CP System (%)	Lactic Acid and ATP-CP System (%)	Oxygen Aerobic System (%)
Marathon	-	5	95
Rowing	20	30	50
Running - 100 m	98	2	-
Running - 1 mile	20	55	25
Running - 3 miles	10	20	70
Running - 6 miles	5	15	80
Skiing Downhill - Racing	80	20	-
Skiing - Cross-Country	-	5	95
Swimming - 50 m	98	2	-
Swimming - 100 m	80	15	5
Swimming - 200 m	30	65	5
Swimming - 400 m	20	40	40
Swimming - 1500 m	10	20	70

Methods of Physical Training

Most people think of exercise as being either aerobic or anaerobic. However, in most types of exercise, a blend of both aerobic and anaerobic exercise is involved. For example, during a 1500 m run, energy is provided by anaerobic metabolism at the

beginning and the end of the run whereas aerobic metabolism supports the middle or the *steady state* part of the run. Aerobic and anaerobic capacity can be improved by using appropriate physical training techniques. The contribution of the three energy systems to the various training methods is shown in Table 1-3. The various physical training techniques are presented below, and can be used for enhancing performance during various physical activities.

Table 1-3. Contribution of the Various Energy Systems According to Training Methods

Training Method	ATP-CP System (%)	Lactic Acid and ATP-CP System (%)	Oxygen Aerobic System (%)
Interval Training*	10-80	10-80	10-80
Sprint Training	90	6	4
Acceleration Sprints	90	5	5
Interval Sprints	20	10	70
Fartlek Training	20	40	40
Continuous Running	2	5-8	90-93
Repetition Running	10	50	40

*Depends on rate and distance of exercise interval, type of relief interval and number of repetitions.

Interval Training

Exercise bouts are alternated with rest or relief periods. Relief periods usually involve mild to light exercise. Generally, in swimming no exercise is performed during the relief periods. The duration, intensity, and number (repetitions) of exercise bouts and the length and type of relief intervals are chosen to suit specific exercise performance requirements. Interval training allows you to exercise at a higher intensity than you could

if you were exercising continuously. This type of training helps to develop the muscle ATP-PC energy system. Both aerobic and anaerobic metabolism can be improved by interval training.

Sprint Training

Sprint training helps develop speed and increase muscle strength. Individuals are required to sprint repeatedly at maximum speed while allowing for complete recovery between sprints. In general, 6 seconds are needed to go from a stationary position to maximum speed. For a runner this would mean running 55 to 60 meters to reach that maximum speed.

Interval Sprints

This method involves alternately sprinting for 45 to 50 meters and jogging for 55 to 60 meters while covering a distance of about 3 miles. Interval sprinting helps to develop aerobic capacity.

Acceleration Sprints

Acceleration sprint training develops speed and strength. Running speed is gradually increased from jogging to striding to sprinting, followed by a recovery walk. This sequence is repeated. Intervals may range from 50 to 100 meters each. For example: 50 meters jogging, 50 meters striding, 50 meters sprinting and 50 meters walking.

Fartlek or Speed Play

The word *Fartlek* means “speed play” in Swedish. It involves running at fast and slow speeds on both level and hilly courses. Unlike interval training, the *fartlek* form of training does not involve specific exercise and rest periods; you do it as desired. For example, you may say to your buddy “I’ll race you to the next stop sign”, and you would both run as fast as you can to that point. You may run at a slower pace for a few minutes, and then run fast again for as long as you want. In other words, it is a speed workout without structure. As such, it is well suited to general conditioning and provides variety to workouts.

Continuous Exercise Training

This type of training is needed to build endurance for activities such as distance running and open ocean swimming. Exercise is performed with distance in mind and may be done at a slow or a fast pace. The aerobic system is the main energy source for this type of activity. Specific training requirements for endurance training in running and swimming will be discussed in Chapters 4 and 5.

Repetition Running

This method is similar to interval training, but unlike interval training, the length of the intervals are longer and usually range from 0.5 to 2.0 miles. Recovery between intervals lasts until the heart rate is under 120 beats per minute, or within 60% of your estimated Max HR.

Conditioning and Deconditioning

Conditioning and deconditioning, also known as training and detraining, are responsible for gains and losses, respectively, in fitness levels. Whereas conditioning is a gradual process and may take six or more weeks to see specific effects, deconditioning occurs relatively quickly. Some of the various metabolic and cardiorespiratory effects of conditioning are presented in Table 1-4.

Table 1-4. Various Effects of Physical Conditioning

Metabolic Changes	Cardiorespiratory Changes
↑ levels of ATP, CP, glycogen	↑ in blood volume
↑ levels of anaerobic enzymes	↓ heart rate at given workload
↑ capacity to tolerate blood lactate	↑ stroke volume
↑ levels of oxygen within muscle	↑ ability to take oxygen from blood
↑ levels of aerobic enzymes	improvement in blood pressure
↑ capacity to use fat as fuel	↑ ability to handle heat load

Effects of deconditioning will be noticed within one to four weeks. Deconditioning reverses the positive metabolic, cardiac, respiratory and muscle enzyme effects that result from conditioning. Some major effects of deconditioning include:

- ◆ Decrease in maximal aerobic capacity - Heart rate for a given exercise workload is higher and the amount of blood pumped by the heart with each beat is reduced.
- ◆ More rapid build up of lactic acid during exercise which leads to earlier fatigue.
- ◆ Reduction in levels of key muscle enzymes which regulate the muscle's ability to generate energy from various sources.
- ◆ Reduced ability to store glycogen in muscle between workouts.
- ◆ Reduced breathing volume which will decrease the amount of oxygen being taken to the exercising muscle.
- ◆ Decreased endurance capacity - time to fatigue is shortened.
- ◆ Decreased ability to dissipate body heat during exercise: the ability to exercise in adverse environments, such as in the heat, is reduced due to all factors mentioned above.

Retraining is necessary to reverse the performance reducing effects of deconditioning. **However, deconditioning can be prevented or minimized by maintaining usual exercise intensity during endurance and strength workouts, when the number or length of work outs is decreased.** Aerobic capacity and decreased lactic acid accumulation during exercise can be maintained by training at least two to three times per week at your usual training intensity. Strength gains can be maintained by including one to two strength training workouts sessions per week. Specific training methods for maintaining fitness under deployed conditions and while overcoming an injury will be discussed in other chapters (see Chapters 11 and 12).

Active Recovery

This type of recovery means that you continue to exercise at a low to moderate (30% to 50% of your maximal heart rate) intensity for several minutes after your regular workout. For example, walk for 5 to 10 minutes after completing a run. The benefits of active recovery and additional information about this type of recovery are provided in Chapter 3: Cardiorespiratory Conditioning.

Chapter 2

SEAL Mission-Related Physical Activities

The primary goal of SEAL physical fitness training is to maximize mission-related performance. SEALs need a physical training program which encompasses all of the various mission-related tasks that need to be performed. Thus, before deciding on a physical fitness training regimen, the specific types of athletic activities involved in your missions must be clearly defined. It is important for you to establish specific goals. An athlete training for a marathon will want to train such that he will finish the race in the shortest possible time. Everything else in your program will be secondary to the primary objective of maximizing lower extremity aerobic performance. Likewise, a kayaker will maximize his aerobic performance by focusing on upper extremity conditioning. A competitive weight lifter, in contrast, will strive to maximize the amount of weight that he can lift, with little or no emphasis on endurance training.

What are “mission-related tasks?”

As an illustration, let's consider bicycling. Cycling is a superb way to obtain an intense aerobic (or anaerobic) workout and is very useful in promoting general cardiovascular fitness, but SEALs do not cycle during missions. No mission scenarios require you to hop on your bike and ride 25 miles. In contrast, a two mile swim in fins also provides an excellent cardiovascular workout, and more closely approximates activities required on Special Warfare missions.

Although a good cardiovascular workout on a bike will confer a training benefit for SEALs, cycling is not the preferred substitute for mission-related training. Being in shape for one activity does not necessarily translate into being in shape for another activity which uses entirely different muscle groups. Training by running or biking to perform a long distance swim will result in a high incidence of muscle fatigue and leg cramps on the mission. Some swimming must be incorporated into a training program. Moreover, swimming with fins on a regular basis will ensure that the operator is comfortable in his fins and wet suit booties, and prevent the development of painful blisters on the mission. Thus, there are many reasons for specificity of training.

Swimming is not the only mission-related task. The goal of this chapter is to present mission-specific activities and determine the physical tasks associated with these missions. **The doctrine that you should train as you fight is also true for physical fitness training.**

Mission-Specific Activities

What sort of physical activities will SEALs be required to perform in the course of their missions? To answer this question, the types of missions that you perform need to be examined. A partial list of these missions is shown in Table 2-1, and a brief description of these missions is provided below.

Table 2-1. A Summary of Various SEAL Missions

Types of SEAL Missions

Small Unit Patrolling

High Speed Boat Operations

Combat Swimmer Operations

SDV and Dry Deck Shelter Operations

Urban Warfare

Winter Warfare Operations

Small Unit Patrolling

One capability that will be needed in almost all SEAL land warfare operations is the ability to carry a substantial amount of weight over long distances. You will typically carry two weapons and a supply of ammunition. There is no good way to know exactly how much ammunition you will be required to carry for a particular mission and SEAL operators tend to pack heavy in this category. In addition, your loads will often include explosives and specialized items. Water needs to be carried in the loadout and, if the mission is a sustained one, rations must also be included. Loads of 70-80 pounds are standard in the community and much heavier loads are not uncommon. How far must you carry this load? There is no one distance that can accurately be used as an upper limit, but certainly 10-20 miles in a 24 hour period, depending on the difficulty of the terrain, may be required for some operations. Walking long distances with a heavy load is a significant challenge in itself, but you may also be required to run and scramble over terrain features, walls, and fences.

Load-carrying is one of the most important physical activities a SEAL can practice.

The ability to carry a wounded fellow operator on your back or shoulders is also important. Buddy shoulder carries are critical in that they are currently the anticipated mode of transporting a wounded SEAL to a secure area where medical care can be rendered. These carries are somewhat different than long distance hikes with equipment because the load is distributed quite differently on the body and in some cases, the weight of the wounded operator may be in addition to the basic load.

How do you train for these activities? Long distance runs with shorts and running shoes are useful in promoting cardiovascular fitness, but do not adequately simulate load-bearing activities. Similarly, the number of bench presses you can do at a given weight does not ensure your being able to walk long distances with a heavy load. Moreover, some of the problems associated with load-carrying are musculoskeletal injuries and blisters. These can only be avoided (or minimized) by practicing the specific activity.

High Speed Boat Operations

The Special Boat Environment imposes unique physical demands. Such missions typically include extended periods in transit, often at high speeds in stormy seas. This type of activity requires extraordinary stability of the knee, elbow, shoulder and ankle joints. Since maintaining a slight bend in the knees, elbows and ankles is essential for minimizing musculoskeletal injuries, training to improve muscle strength and endurance is critical.

Combat Swimmer Operations

With the current-day SEAL teams having had their origin in the Scouts and Raiders, Naval Combat Demolition Units, and Underwater Demolition Teams of World War II, it is not surprising that combat swimmer operations are still an important part of the Naval Special Warfare mission. These operations may last as little as one or two hours in some situations, and as long as eight to 10 hours in others. You may be swimming on the surface or swimming underwater compass courses with the Dräger LAR V or MK 16 closed-circuit underwater breathing apparatuses. These operations are often carried out in very cold water; thus, hypothermia is a constant concern. In many instances, you will be towing something in the water (usually something with a very rapid rate of combustion), thereby increasing the effort needed to accomplish the mission. Some missions involve exiting the water and climbing up the side of a ship using a caving ladder or other climbing apparatus. These are difficult maneuvers under any circumstances, but much more so when your hands are numb from cold exposure and you are climbing with weapons, ammunition, and explosives. **Regular exposure to cold water immersion will help to develop physiological adaptations so that you will fare better when subjected to cold water on a mission.** In addition, both upper body and leg strength are important for shipboarding techniques. **Grip strength, in particular, is critical for maintaining a firm hold on the rope or ladder.** Caving ladder or rope climbs are very important to develop the muscle groups that will be used for shipboarding; you should do these climbs with gear whenever possible.

Swimming with fins is an activity basic to all SEAL combat swimmer missions and should be done on a regular basis in team physical training evolutions. Swimming without fins, while a very good activity for promoting cardiovascular fitness, is not typically required for SEAL missions. It is important to mention that encouraging speed on combat swimmer operations is fine for surface swims, but should not be done on underwater swims because of the reduction in the LAR V operating range and increased risk of central nervous system oxygen toxicity.

High exercise rates under water increase the diver's chance of having an oxygen convulsion.

SDV and Dry Deck Shelter Operations

These operations are basically combat swimmer operations, but ones in which the SDV does the majority of the work. They are typically longer than operations in which free-swimming divers are used, but this is not always the case. As SDV operators, you need to be able to accomplish the same physical tasks noted for combat swimmers above. In addition, these operations may require significant upper body strength to handle the heavy equipment required for the mission both in the Dry Deck Shelter and later at the objective.

Urban Warfare

Some SEAL missions call for direct action operations in an urban setting. Although it is difficult to generalize, these missions might be expected to require less of a load-bearing challenge because some form of transportation will often be available. In addition, the distance to be covered on foot will typically be less than many remote missions. Generally, you will need to carry less food and water than with other types of land warfare missions. Your need for weapons and ammunition, however, will not be reduced, so significant gear loads are still a possibility. Additionally, you may need to perform demanding physical tasks, such as sprints and rapid stair climbs, in the urban warfare setting. Moreover, there is the potential of having to accomplish these maneuvers while carrying or dragging a wounded buddy or hostage.

Winter Warfare Operations

Winter Warfare operations often require long distance cross-country skiing or snowshoeing which will usually have to be done with a heavy equipment load. This activity requires the use of a different set of muscles than walking and running. Not all SEAL units have a primary mission area that requires the ability to operate in winter warfare environments, but those that do should consider cross-country skiing with equipment when designing their workout programs (see Chapter 14).

Specific Mission-Related Physical Tasks

In order to identify the physical demands of direct action SEAL operation, a study was undertaken in early 1990 by the Naval Health Research Center. Missions and the physical requirements (i.e., aerobic and anaerobic components) necessary to complete each mission and mission segment were evaluated. In brief, a total of 82 SEALs, averaging 11 years of experience, participated in the study. Subject matter experts from operational platoons were interviewed regarding missions they had conducted as SEALs. Information obtained during these interviews provided the basis for a questionnaire which was developed and given to the study participants. The questionnaire was composed of a list of missions and mission segments such as “fast rope to the deck of a ship from a height of 40 feet, carrying a 50-pound pack.” Each SEAL participant ranked mission and mission segments on scales to rank: difficulty of performance, frequency of performance, and importance to mission success. The individual scores for each scale were then summed to obtain a “composite score”. Mission tasks that received the highest composite scores are provided below.

- ◆ Walk (i.e., hump) 15 km over uneven terrain at night carrying a 125 lb pack to objective in 70°F, then retrace steps to extraction point.
- ◆ Serve as point person for an element, walking a distance of 42 km through dense jungle in tropical heat and humidity over a 3-day period carrying a 60 lb pack and weapons.
- ◆ Swim a distance of 2,000 meters in 56°F carrying a limpet mine and using a Dräger; return to Zodiac without limpet, then travel 6 km to extraction point.

- ◆ Swim for 3 hours underwater (temperature: 70°F), wearing a wetsuit, mask and fins, and using a Dräger UBA and attack board.
- ◆ Drag a fully-loaded F470 Zodiac 50 meters onto a rocky beach with five other SEALs, then, with three of the boat crew, quickly move all equipment and supplies across 200 meters of rocky beach and stage/cache gear in preparation for the overland phase of the mission.
- ◆ Perform a rescue drag of a wounded comrade weighing 170 lbs, dragging him by the web gear a distance of 75 meters, with the assistance of one other SEAL.

Given the above list of missions tasks, the question “**what are the physical fitness requirements necessary to complete each task?**” was asked. A summary of the physical tasks data is presented in Table 2-2 and Table 2-3. Table 2-3 presents the numerous physical tasks associated with the missions and the physical characteristics demanded of the SEAL. Table 2-3 extends these characteristics by delineating specific training plans to improve performance on the physical tasks.

Table 2-2. Physical Requirements for Specific Missions and Mission Elements

Mission	Physical Tasks	Physical Requirements
Small Unit Patrolling	Sprint with gear Fast roping Load bearing Long distance hike “Over the beach” Buddy carry Rock climbing	Leg endurance Shoulder/arm strength Shoulder/arm endurance Upper back strength Grip strength
Combat Swimmer	Caving ladder climbs Underwater swimming Surface swimming	Shoulder/arm strength Leg endurance Grip strength
SDV/Dry Deck Shelter	Underwater swimming Heavy equipment handling	Leg strength/endurance Shoulder/arm strength
Urban Warfare	Buddy shoulder carry Climbing buildings Running/sprinting with gear Stair climbing	Shoulder/arm strength Leg strength/endurance Grip strength
High Speed Boats	Maintain joint stability at high speeds Extended periods in transit	Shoulder/arm strength Shoulder/arm endurance Leg strength/endurance Grip strength
Winter Warfare	Snow shoeing with gear Skiing with gear	Upper back strength Upper back endurance Leg strength/endurance Shoulder/arm strength Shoulder/arm endurance Grip strength

Table 2-3. Specific Physical Task-Related Training

Physical Tasks	Task-Related Training
Run/sprint with gear Load bearing Long distance hike “Over the beach” Buddy shoulder carry Obstacle negotiation with gear	Running/intervals Weight training Plyometrics Load-bearing hikes Grip strength
Fast roping Caving ladder Rock climbing Climbing buildings	Grip strength Rope climbs Squeezing tennis balls Weight training O’course
Swim with fins Underwater swimming Swimming with load	Surface swims Underwater swims
Snow shoeing Skiing with gear	Cross-country skiing Distance running Load-bearing hikes Weight training
Maintain joint stability at high speeds	Weight training Grip strength

The critical point in these tables is that your physical training program must be a whole body conditioning program with upper and lower body endurance, flexibility, and strength activities. Most missions involve multiple physical tasks, therefore, an effective training program must address the physical requirements of all these tasks. The training program provided in the last chapter has been designed with this goal in mind.

SEAL training must be whole body conditioning with upper and lower body endurance, flexibility, and strength activities.

Summary

The most important types of SEAL mission-related athletic activities are listed below. Each of these activities should be incorporated into a training program, ideally on a weekly basis. For other/substitute activities, please refer to Chapter 15: Physical Fitness and Training Recommendations.

- ◆ Long distance hikes with heavy equipment loads.
- ◆ Cross-country skiing with equipment.
- ◆ Caving ladder climbs with gear.
- ◆ Swimming with fins.
- ◆ Sprints with gear.
- ◆ Obstacle negotiation with gear.
- ◆ Fast-roping.

For more information you may wish to consult the Navy Technical Report: No. 95-24 entitled: “Physical Demands of U.S Navy Sea-Air-Land (SEAL) Operations,” WK Prusaczyk, JW Stuster, HW Goforth, Jr., T Sopchick Smith, and LT Meyer.

Chapter 3

Cardiorespiratory Conditioning

The American College of Sports Medicine (ACSM) and the Centers for Disease Control and Prevention recently formulated new guidelines for the American public with respect to exercise. The new recommendations state that “*Every US adult should accumulate 30 minutes or more of moderate intensity physical activity on most, preferably all, days of the week*”. They defined moderate intensity physical activity as “activity performed at an intensity of 3 to 6 METS, or the equivalent of brisk walking at 3 to 4 m.p.h. for most healthy adults”. Whereas the previous recommendations for the US population emphasized the importance of extended periods of strenuous exercise, these new guidelines state that short, intermittent bouts of moderate exercise are important and sufficient for health benefits. The overall goal of these organizations is to promote cardiorespiratory conditioning, an important aspect of overall fitness, health, and disease prevention. However, activity above and beyond the recommendations for the public is necessary for SEALs and other highly competitive athletes. In this chapter we will discuss:

- ◆ Basic concepts of cardiorespiratory conditioning.
- ◆ How to estimate your maximal aerobic capacity.
- ◆ Types of aerobic activities and basic workouts.

Many of the definitions and terminology associated with cardiorespiratory conditioning have been presented in Chapter 1. However, other terms are used interchangeably to reflect cardiorespiratory conditioning; these include cardiovascular, cardiopulmonary, and aerobic conditioning. The important point is that this form of conditioning improves health and work capacity by enhancing the circulation and overall functioning of the heart and lungs.

Basics Concepts of Cardiorespiratory Exercise

Cardiorespiratory conditioning consists of both aerobic exercise, which requires oxygen to sustain muscle activity, and anaerobic exercise, which does not use oxygen for the short bursts of highly intense activity. Most daily work and activities are aerobic in nature, and thus, improving the delivery of oxygen to the working skeletal muscle will improve work performance. Your ability to utilize oxygen for exercise depends on a variety of processes including:

- ◆ Functioning of your muscles of respiration or pulmonary ventilation.
- ◆ Ability of oxygen to diffuse across lungs into your blood.
- ◆ Ability of heart to increase rate of beating and amount of blood pumped with each beat.
- ◆ Ability of blood vessels in and surrounding skeletal muscle to regulate blood flow.
- ◆ Ability of contracting skeletal muscle to extract and use oxygen in blood.

All of these factors are important in determining your ability to sustain a submaximal workload, and your maximal aerobic capacity. Two other factors which help determine maximal aerobic capacity are your percentage of specific muscle fiber types and your genetic makeup. Some persons are endowed with a high aerobic capacity, whereas others are not. However, everyone can and will improve if a cardiorespiratory conditioning program is followed.

Terms Related to Conditioning

Many terms are used to define or describe exercise conditioning and work rate, also referred to as exercise intensity or work load. The two terms used throughout this chapter for describing how to gauge your work rate will be maximal oxygen uptake and energy expenditure as calories/hour, or kcal/hr. Other terms to describe work rate and their interrelationships will be discussed at the end of this chapter.

Maximal Oxygen Uptake

The primary measure or predictors of one's capacity to sustain work performance is maximal oxygen uptake ($\text{VO}_{2\text{max}}$) or maximal aerobic (cardiorespiratory) capacity. $\text{VO}_{2\text{max}}$ is measured in **milliliters per minute** (ml/min), **Liters/min**, or after adjusting for body weight in kilograms, as **ml/kg/min**; a higher value indicates a higher level of cardiorespiratory fitness.

**Your maximal aerobic capacity or oxygen uptake
is the best indicator of how much work you
can sustain without fatigue.**

Typical $\text{VO}_{2\text{max}}$ values range from 30 ml (of oxygen)/kg/min for an unfit person up to 80 ml/kg/min for an exceptionally fit, endurance athlete. If the unfit and highly fit persons both weighed 70 kg (155 lb) then their respective absolute maximal aerobic capacities would be 2.1 liters (of oxygen)/min and 5.6 liters (of oxygen)/min.

**Using 1 liter of oxygen/min is equivalent
to expending 5 kcal/min**

As such, the unfit person can only work at a rate of up to 10 kcal/min (2.1 L x 5) whereas the highly fit could work at up to 25 kcal/min (5.6 L x 5 kcal) if needed. If a specific task required 2 L/min, then this would amount to 10 kcal/min of energy. Resting energy expenditure requires less than one kcal/min, or about 0.200 to 0.250 L (of oxygen)/min. In order to account for different body sizes, resting energy expenditure for an individual is usually defined as:

3.5 ml of oxygen/kg body weight/minute.

Thus, for a 70 kg (155 lb) SEAL, resting energy expenditure would be approximately 245 ml/min or 0.245 L/min (3.5 x 70). This is equivalent to expending around 1 to 1.25 kcal/min.

Anaerobic Power

How much strenuous work can you sustain without oxygen? Most people can do very little for more than a couple of minutes. It is very important to realize that most people cannot work for very long at even 90% of their maximal aerobic capacity. This is because everyone has a threshold at which the balance between aerobic and anaerobic energy systems begins to favor the anaerobic; your muscles cannot extract enough oxygen to produce the required energy. This is called your **anaerobic threshold**; the turning point can be monitored by the accumulation of lactate in your blood. Of course, your body will know when there is too much lactate, because once lactate goes above a certain value, it starts to accumulate and unless you decrease your work rate, you will become too tired to continue working.

This anaerobic threshold, or “break point” varies among individuals, but ranges between 60% and 100% of your VO_{2max} ; all SEALs should be able to work at 70% of their VO_{2max} for an extended period, and should have a break point above 70%. Conditioning programs for SEALs should strive to raise the anaerobic threshold or break point to as high as possible, because that means you can work at a higher rate for a longer period of time.

Interval workouts stress the anaerobic energy systems and will increase your anaerobic threshold and power.

Interval and fartlek workouts for running and swimming are described in their respective chapters, and such workouts for other forms of exercise are described later in this chapter.

Determination of Work Rate

One common denominator across all types of cardiorespiratory conditioning programs is exercise intensity and work rate. The term exercise intensity typically refers to how hard you are working as a percent of your maximal aerobic capacity. For example, you could work at an intensity equivalent to 50% (easy), 70% (moderate), or 90% (strenuous) of your maximal aerobic capacity or maximal heart rate. You will learn how to estimate your maximal aerobic capacity below, but on average, a maximal capacity of 45 to 55 ml of oxygen/kg/min and a maximal heart rate of 200 beats per min would be typical for a 20 to 29 year old SEAL. Table 3-1 presents the relation between exercise intensity, oxygen uptake, and heart rate for a 20 year old SEAL with a maximal heart rate of 200 and a maximal oxygen uptake of 55 ml of oxygen/kg/min. Easy exercise would use 25 to 30 ml

of oxygen/kg/min or a heart rate of about 130 bpm, whereas strenuous exercise would require a heart rate of around 180 bpm. However, you must know your maximal capacity or your maximal heart rate to actually quantify your exercise intensity in this way.

Table 3-1. Example of the Relation Between Exercise Intensity, Aerobic Capacity and Heart Rate

Exercise Intensity (% of Maximal)	Oxygen Uptake (ml/kg/min)	Heart Rate (bpm)
100% - Maximal	55	200
90% - Strenuous	50	187
70% - Moderate	39	160
50% - Easy	28	131

Factors Affecting the Training Response

The terms duration, frequency and intensity are commonly used when talking about training for fitness or health. All training programs, whether running, biking, swimming, or climbing, strive to vary in duration, frequency, and intensity so as to optimize conditioning and minimize injuries. Five major factors determine the extent of your maximal aerobic capacity and the magnitude of your response to training. These include:

- ◆ Initial level of aerobic fitness.
- ◆ Duration of exercise.
- ◆ Frequency of exercise.
- ◆ Intensity of exercise.
- ◆ Genetics/heredity.

General principles apply to all types of physical activities. Take the following general principles and apply them to your individual program.

- ◆ The degree of aerobic training is closely tied to intensity and total work, not to frequency of training. However, a minimum of 3 days per week is recommended.
- ◆ A greater training improvement (up to a point) will be noted if you exercise above 85% of $\text{VO}_{2\text{max}}$ or 90% of your maximal heart rate once a week or every other week: interval training.
- ◆ Aerobic capacity will improve if exercise increases your heart rate to at least 70% of your maximum heart rate.
- ◆ A lower exercise intensity can be offset by exercise of longer duration.
- ◆ Maximal heart rate for swimming and other upper body exercise is lower than maximal heart rate for leg or whole body exercise. Thus, training heart rate (THR) can be 13 to 15 bpm lower for swimming/upper body exercise than when running, biking, or other whole body exercises.
- ◆ A threshold duration per workout has not been identified to maximize aerobic capacity.

Active Recovery

Throughout this guide, we will continually stress the importance of warming up, cooling down, and stretching. These are integral parts of any workout, regardless of the activity. The cool down, or recovery period, is very important because it will determine how you feel several hours after your workout. There are two types of recovery: active and passive. Passive recovery, in other words, just resting, was recommended many years ago, and is still recommended when you exercise below 50% of maximal capacity. Active recovery is now preferred for exercise exceeding 60% of maximal capacity to accelerate removal of lactate. This may help prevent muscle cramps, stiffness, and preserve performance during subsequent strenuous exercise.

Active recovery involves exercising at 30% to 50% of maximal capacity for 5 to 10 minutes after a strenuous workout.

Blood lactate removal after strenuous exercise is accelerated by active recovery: mild aerobic exercise.

How to Estimate Your Maximal Aerobic Capacity

Exercise testing is often conducted for assessment of cardiorespiratory fitness. Types of protocols currently used to assess cardiorespiratory fitness or aerobic capacity are **incremental work rate tests**, where the exercise work rate is increased by a uniform amount at predetermined time intervals, and **constant work rate tests**, where the subject works at a submaximal constant work rate for a specified time period. Your heart rate at the specific work rates are used to estimate maximal oxygen uptake. Although the most accurate test is conducted on a treadmill, a bicycle will give a good estimate. If you have access to a stationary bicycle, you can test yourself by using the incremental test protocol described. Although it is best to use a heart rate monitor, you can manually take your pulse at various times during the test.

Bicycle Exercise Test Instructions

This test is an incremental submaximal test with four stages; each stage lasts two minutes. If desired, you can continue to increase the work rate and exercise for five to six stages. If you use a bike that monitors revolutions per min (RPM), your RPM must be maintained at 60. This seems like a slow pace, since you would usually bike at 70 RPM, but in order to achieve the desired work rate, 60 RPM pace is critical. Whatever type of bike you use, you must check to determine how to regulate **kcal/hr**.

Test Procedures

Adjust height of seat and handle bars to fit you, then if available, hook up a heart rate monitor and then start pedaling at a comfortable workload (See Table 3-2). If the bicycle permits, key in your body weight. This will make the test more accurate. After a couple minutes of warm-up, begin to exercise at level 1 or around 450 kcal/hr (± 25 kcal/min); record heart rate after two minutes (end of stage one). Increase the workload to level 2 or approximately 550 kcal/hr and continue for two more minutes. Remember that all stages are 2 minutes, so proceed to levels 3 (650 kcal/hr) and 4 (750 kcal/hr) at the appropriate time. The test should take no longer than 8 minutes, after warming-up. Record your heart rate at the end of each stage (Table 3-3).

**DO NOT STOP Pedaling While
Recording Your Heart Rate.**

Table 3-2. Stages and Work Rates for Cycle Ergometer Exercise Testing

Stage	Work Rates
0	Warm-up
1	450 kcal/hr
2	550 kcal/hr
3	650 kcal/hr
4	750 kcal/hr

Table 3-3. Cycle Ergometer Test Form

Name:_____	Age:_____
Weight in kg [*] :_____	Estimated Max HR ^{**} :_____

Stage	Kcal/hr	Heart Rate
1	450	
2	550	
3	650	
4	750	

^{*}To convert your weight from pounds to kg, divide by 2.2. ^{**}Estimate your maximal heart rate as 220 - your age.

Estimating Maximal Aerobic Capacity

Look at the example in Figure . Heart rate has been plotted against each energy expenditure. Estimate your maximal heart rate as 220 - YOUR AGE. Plot your heart rate values at each kcal/hr and draw the line of best fit through your points as in Figure (This should be a fairly straight line). Extend the line so you can also plot your estimated maximal heart rate on the line. Estimate your maximal aerobic capacity (in L/min), and then normalize for body weight: divide your $\text{VO}_{2\text{max}}$ by your weight in kg. For example if your maximal oxygen uptake was 4.2 L of oxygen/min (4,200 ml) as in the examples below, and you weigh 85 kg, your normalized maximal oxygen uptake would be 4.2 L or 4,200 ml/85

= 49 ml/kg/min. To convert your weight in lb to kg divide by 2.205. Normalizing for body weight allows you to determine how you rate relative to other persons of your age (Consult Table 3-4).

Example of How to Estimate Maximal Oxygen Uptake for an 85 kg, 24 year old SEAL

Table 3-4. Cardiorespiratory Fitness Classification: Maximal Oxygen Uptake (ml/kg/min)

Age	Low	Fair	Average	Good	High
20-29	<25	25-33	34-42	43-52	53+
30-39	<23	23-30	31-38	39-48	49+
40-49	<20	20-26	27-35	36-44	45+
50-59	<18	18-24	25-33	34-42	43+

Figure 3-1. Plot Your Heart Rate to Estimate Maximal Oxygen Uptake

Types of Aerobic Activities and Basic Workouts

Outdoor Activities

Aerobic activities, other than running and swimming, are briefly described below. More extensive discussions are provided in the section on indoor activities, since equipment used indoors typically has information about work rate and intensity. However, Table 3-5 presents the amount of energy expended per hour (kcal/hr) in these activities as a function of work rate. The values are for a 70 kg male. To get a more accurate estimate for yourself, multiple the number by your weight in kg and divide by 70.

Table 3-5. Typical Energy Requirements for Various Outdoor Activities

Activity	Work Rate	Energy Expenditure (kcal/hr)
Bicycling	6 mph	270
	10 mph	420
	20 mph	720
Cross-Country Skiing	Moderate	504
	Strenuous, Uphill	1140
Jumping Rope	70 Jumps/minute	690
	145 Jumps/minute	840

Bicycling

Bicycle riding, or biking, is an excellent activity for improving overall cardiorespiratory fitness. Importantly, indoor bicycle ergometers have been used for many years to study the responses of the body to exercise. The work rate you maintain while biking varies according to the terrain and your motivation. As such, biking outside offers

many challenges. It is also a very efficient means of locomotion: the energy cost of biking is only 20% of walking, but you can travel almost five times faster on a bicycle. The quadriceps muscle in the front part of the thigh is the primary muscle for high rates of power output, and seat height can markedly affect overall muscle involvement. Although pedaling rates vary from 40 to 100 RPM, a rate of 70 appears to be the most comfortable.

A high pedaling rate offers advantages in terms of a high power output.

All in all, biking is a great alternative to running, and should be considered as a suitable activity for maintaining fitness, even if it is not part of a SEAL's mission. Biking complements other activities and is often used in rehabilitation from other musculoskeletal injuries. More details with respect to biking will be provided under the section on stationary cycles.

Cross-Country Skiing

Although cross country skiing is discussed in detail under winter warfare below, it should be noted that this is an excellent method of training for cardiorespiratory fitness. It engages almost all of the major muscle groups and thus, the overall energy expenditure may be as high or higher than when moving the body over the same distance on foot. Importantly, the intensity of the effort varies greatly as a function of the terrain: climbing uphill requires tremendous effort whereas going downhill represents a light load. High caliber cross-country skiers have some of the highest maximal oxygen uptakes ever recorded (see Chapter 2). However, the appropriate equipment and environment are necessary for cross-country skiing.

Jumping Rope

Jumping rope is a great way to maintain fitness on board a ship or in confined spaces. It can provide a high intensity, cardiorespiratory workout if done long enough and fast enough. If the pace is fast, it is equivalent to running in terms of energy expenditure.

Jumping rope does not have to be boring, especially if you use different types of jumps. Table 3-6 provides the names and an explanation for alternatives to the basic jump.

Table 3-6. Different Types of Jumps for Jumping Rope

Type of Jump	Description
Boxer's Dance	With both feet together, shift weight from right to left with each jump.
Run	Jump to the left while lifting left knee, then switch.
Shuffle	Start with right foot forward and left foot back, then switch each jump landing on both feet at same time.
Knee-Toe	Tap right toe on the floor, then jump from your left foot to your right; at the same time lifting left knee as high as possible. Switch legs.
Double Rotation	Twirl the rope around twice between each jump.
Jumping Jack	Jump two times with feet together, then do a jumping jack every third time.

In terms of gear, many different types of rope are available, and rope jumping can be limited by the quality of the rope. Most experts recommend lightweight leather ropes. Believe it or not, many books have been written about jumping rope, with basic to advanced skills, drills and moves. Overall, jumping rope is a great activity, especially if you are in a confined environment.

Stationary Exercise Alternatives

Rowing Ergometer

There are many types of rowing machines on the market, and each has distinct advantages and disadvantages. The best rowing machine is one with variable resistance and the ability to regulate rowing rate. Most provide feedback on either watts or calories per hour, as well as meters covered. Proper technique is critical so as not harm your lower back. If proper technique is maintained, cardiorespiratory conditioning can easily be achieved. In fact, both the upper and lower body are exercised, and it promotes flexibility by emphasizing maximum joint range of motion, so it is a total body workout. It is also impact-free so it is a great alternative to running! Some key points to remember are:

- ◆ The motion of the entire stroke should be fluid.

- ◆ A stroke rate between 24 and 30 per minute should be the goal.
- ◆ Your grip should be loose and comfortable with wrists level.
- ◆ The rule of thumb should be a longer not a harder workout.

Just plain rowing can become a bit boring, but there are many ways to make it fun and varied. Table 3-7 presents descriptions of various workouts for a rowing ergometer.

Table 3-7. Various Workouts for a Rowing Machine

Workout	Description
Steady State	20 to 40 minutes at a pace which barely allows you to chat with a partner.
Intervals	3 to 5 sets of 300 to 500 meters at a fast pace with 2 minutes of rest between each set.
Fartleks	Alternate 1 minute hard and 1 minute easy for 20 minutes.
Long and Slow	6,000 meters at an easy pace.
Time Trial	2,000 meters at a record pace.
Pyramids	1 min hard, 1 min rest, 3 min hard, 2 min rest, 5 min hard, 3 min rest, 7 min hard, 5 min rest, 5 min hard, 3 min rest, 3 min hard, 2 min rest, 1 min hard.

How do you know if the workout is hard or light? Your body is the best judge, but knowing the kcal/hr will also help. A pace of 500 meters/4 minutes would be a light workout whereas a pace of 500/2 minutes would be strenuous. These paces equate to 385 and 970 kcal/hour for a 70 kg man.

Bicycle Ergometers

Cycle ergometers have been around a long time, and are still the mainstay in exercise/fitness testing. Monitors on the bicycles available today typically display kcal per hour. Table 3-8 presents kcal/hour values for stationary bicycle workouts at various intensities. These values can be used to gauge your work rate during indoor biking.

Table 3-8. Energy Expenditure (kcal/hr) for Stationary Cycling at Various Intensities and Body Weights

Body Weight (lbs)	Intensity			
	Light	Moderate	Vigorous	Strenuous
155	320	450	600	770
175	360	520	680	880
200	400	590	760	990
220	450	650	850	1100

Treadmills

Despite the fact that it is much nicer to run outside than inside, the treadmill is an extremely efficient way to maintain and/or improve cardiorespiratory conditioning. Unlike the cycle and rowing ergometer, jogging or running on a treadmill is weight dependent: the energy expended is determined by your body weight. In addition, it is an impact sport and should not be the only form of conditioning, so joints are protected and injuries minimized. However, if you are on a ship or in another type of confined space, a treadmill could maintain your fitness!

What kind of workouts should you do on a treadmill? Three days per week is more than enough, if you do other types of exercise on off days. On a treadmill, you can mix up your pace and/or change the resistance by changing the incline. The incline and speed will determine the intensity of the workout. Remember, a strenuous workout is over 750 kcal/

hr, and a moderate workout would be 450 to 600 kcal/hr. Table 3-9 presents kcal/hr values for treadmill workouts. These values can be used to determine the speeds and grades for indoor running.

Table 3-9. Approximate Energy Requirements (kcal/hr) for Horizontal and Uphill Running on a Treadmill

% Grade	Speed (mph)				
	4	5	6	7	8
0	425	515	610	700	800
2.5	470	570	670	775	880
5.0	510	620	740	850	970
7.5	550	670	800	920	1045
10.0	600	720	850	990	1125

Ski Machines

The simulated skiing machine provides an excellent mode of exercise for whole body conditioning. It uses both the upper and lower body, and offers a range of settings so your workout can be light, moderate, vigorous or exhausting. Maintaining a comfortable rhythm is most important during a moderate workout, and is essential for progressing to a strenuous workout. Importantly, unlike running outside or on a treadmill, minimal stress is placed on the joints. Most models have various settings for modulating leg resistance, and typically the resistance ranges from four to 32 lbs. Once you have determined your desired resistance the intensity of your workout will be determined by your average speed. Numerous tables are available which allow you to determine the number of calories expended per minute at various resistance settings and speeds. However, they are far too detailed to include here. Table 3-10 presents the kcal/hr expenditures for various settings and speeds for a 70 kg (155 lb) man. These values can be used as to estimate your actual work rate.

Table 3-10. Energy Expenditure (kcal/hr) on a Ski Machine at Various Settings and Speeds

Setting	Speed (kilometers per hour)					
	5	6	7	8	9	10
3	485	530	575	620	670	710
4	550	600	645	690	735	780
5	620	660	710	755	800	850
6	680	730	775	820	865	910
7	750	800	840	885	930	975
8	815	860	905	950	1000	1045

Some indoor skiing machines also have multiple settings for arm resistance, and adjustments to these settings should be made to ensure a moderate to vigorous workout. However, kcal/hr expenditure for arm settings becomes quite complicated and will not be presented here. All in all, ski machines provide great exercise, and would be extremely beneficial for SEALs involved in winter warfare training.

Stair Steppers

Stair steppers provide an excellent alternative to running, biking, and other forms of aerobic exercise. Although stair-stepping is a weight-bearing exercise, the impact is much less than with running. However, to get the full effect, instructions must be followed. Most people hang on to the handles and this diminishes the conditioning effect. An equally good workout could be gained by actually climbing real stairs for the same period of time; many people climb stairs without holding the handles, and thus carry their full weight up the steps. By hanging on, you allow your arms to support a portion of your body weight and the energy demands are less.

Most stair steppers have a variety of computerized, pre-designed programs to meet the needs of devoted users. There are interval training programs, climbing programs, manual programs, and many other creative exercise programs to vary the intensity of the exercise. Although each manufacturer has its own energy cost equations, the way to determine work intensity is to determine the number of steps per minute; one step is typically 8 inches of vertical climb. A low intensity exercise would be a step rate of less

than 35 steps/minute, whereas a high intensity workout would require a step rate in excess of 95. This is not an easy exercise routine. Table 3-11 presents the approximate energy expenditure in kcal/hr for a 155 lb SEAL at various stepping rates.

Table 3-11. Energy Expended (kcal/hr) during Stair Stepping at Various Step Rates

Step Rate in Steps/minute	35	60	95	120	140
Approximate kcal/hr	250	390	580	730	820

Climbers

Workouts on a climber will build upper body strength and provide excellent cardiovascular conditioning. Different types of climbers are available, and each has specific characteristics. Regardless of which variety is used, climbers have common features: weight dependent exercise that conditions primarily the upper body.

Energy expenditure on a climber depends on your speed of climbing and your body weight. Some authorities would say that climbing results in a greater energy expenditure than most other activities, but this depends on your strength and how hard you work. Table 3-12 provides kcal/hr at selected weights and ascent rates.

Table 3-12. Energy Expended (kcal/hr) on a Climber at Designated Weights and Feet per Minute

Weight in lbs	Feet Climbed Per Minute					
	40	60	80	100	120	140
140	360	480	600	690	810	930
160	420	520	670	800	930	1050
180	460	600	750	900	1050	1200
200	510	670	840	1020	1170	1320
220	570	750	930	1100	1270	1450

Basic Workouts

The most important issue with respect to workouts is recovery. Rest is an exceedingly important factor in recovery from strenuous workouts, so back-to-back high intensity workouts are not encouraged. Experts recommend a hard day followed by an easy day, and at least one day of rest over a seven day period. This can be an excellent plan, but you should also let your body be your guide. Some days when you go to workout and feel great, this day can and should be a hard workout day. On other days when it is an effort to even get your workout clothes on, this should either be a rest day or an easy day.

Easy days could be a run, bike, or swim at a very comfortable pace for 60 minutes or more, an easy short workout, or a short hump with a light load. A hard day may be intervals, fartleks, a fast pace for a specified period of time, a long hump with a heavy load, or a competition among team members. The key is to make it fun, challenging, and interesting.

Other Terms for Work Rate

Other terms are frequently used to describe exercise intensity and work rate. These include:

- ◆ Work
- ◆ Power
- ◆ METS
- ◆ Watts

If these terms and concepts are learned, they will apply to almost all exercise equipment and conditioning programs. The terms work and power are often used incorrectly. Because these terms can be expressed in a variety of ways, it is useful to understand or at least be familiar with the basic units of measurement.

Work and Power

Work = Force x Distance and is measured in kcal

Power = Rate of Doing Work and is measured in watts

METs and Watts

The term MET, which was used in the national recommendations for exercise, is often used to estimate energy expenditure and work rate.

A MET is defined as a multiple of resting metabolic rate or energy expenditure.

One MET is between 0.200 to 0.250 liters (of oxygen)/min, or approximately one kcal/min, depending on the weight and body type of the person. Two METS would be two times resting metabolic rate or approximately 0.5 liters (2 X 0.200 to 0.250) of oxygen/min, or 2 kcal/min. Likewise, 3 METS would be 0.75 liters (3 X 0.200 to 0.250) of oxygen/min, or around 3 kcal/min.

Watts, as stated above, are units used to quantify the rate of doing work, or work/time. Most new exercise equipment express work rate in terms of watts, although many use METS instead of or as well as watts. Table 3-13 presents the relationship between various terms denoting exercise intensity. These can be used to monitor exercise intensity.

Table 3-13. Workload Conversion Sheet

Watts	Oxygen Uptake (L/min)	Work Rate	Energy Output (kcal/hr)	METS
50	0.9	Easy	270	4.0
100	1.5	Fairly Easy	450	6.7
150	2.1	Moderate	630	9.3
200	2.8	Moderately Hard	840	12.4
250	3.5	Very Hard	1050	15.5
300	4.2	Very, Very Hard	1260	18.7

Summary

No doubt new modes of exercise will be appearing in the future. What you chose to use will depend on many factors. The important issue is whether you are able to achieve the desired work rate and conditioning level. A recent study of indoor exercise machines examined energy expenditure at given ratings of perceived exertion. They compared a treadmill, a rowing ergometer, a combination cycle/arm ergometer, a cycle ergometer, a stairstepper and a skiing machine. Surprisingly they found that rates of energy expenditure varied by as much as 261 kcal/hour for the exercise machines when subjects exercised at self-selected work rates corresponding to fairly light, somewhat hard, and hard. The treadmill came out with the greatest energy expenditures, followed by the rowing and stairstepping ergometers; the cycle and combination cycle/arm ergometers came out with the lowest values. If exercise intensity is established by perceived effort, treadmill running/walking will result in greater energy expenditure and a stronger cardiorespiratory training stimulus for a given duration of exercise as compared to other modalities.

Chapter 4

Running for Fitness

Running is a fundamental part of your physical training program and provides an excellent aerobic workout. Moreover, it is not expensive; most of the cost of running involves buying a pair of “good” running shoes. If you train intelligently and have the right gear, you can continue to enjoy the fitness and general sense of well-being that accompanies running while avoiding running injuries. In this chapter, basic information is provided for maintaining a sound, middle distance running (20 to 40 miles/week) program; this is adequate for running 10K and half marathon races. Some of you may consider running a marathon in the future; at such a time you may want to get training tips from experienced marathoners, trainers at a running club or running magazines.

Running Gear

Running Shoes

A good pair of running shoes will provide shock absorption, cushioning, motion control and durability, and ultimately help prevent injuries. Under no circumstance should you buy shoes if they do not fit correctly. Running magazines usually have a yearly review of various running shoes, newest models of shoes and the type of runner the shoes are most suited to. You can also obtain current information from “Running Sites/Pages” on the worldwide web. It is wise to try on several different shoes at a sporting goods store to determine which one might be best for you. This is also important if you are planning to buy shoes from a catalog.

Pronation

It is important to understand this term because the type of running shoe you buy depends on whether you are a normal, over-, or under-pronator. While running, the outside of the heel strikes the ground first. Next, the foot rotates inward and downwards: this process is called pronation. Everyone pronates to some degree and pronation helps the foot absorb the shock of impact. However, some runners over-pronate: their feet roll too far inward. Put your running shoes together and look at their heels/back; if they lean inward, you are probably over-pronating. Another way to check pronation is to have a friend run behind you and have them watch the back of your heel as it makes contact with the ground: the greater the inward roll of your heel, the more you pronate.

Excessive pronation can lead to injuries of the lower leg and knee.

Other runners under-pronate or their feet do not have enough inward roll after striking the surface. Such individuals are considered to have “rigid” feet or feet that absorb shock poorly. Shoes are available to correct for either under or over-pronation.

Shoe Terminology

When buying running shoes, it is helpful to be familiar with some common terms. Figure 4-1 presents the various parts of a running shoe.

Figure 4-1. Parts of a Running Shoe

Some General Terms

- ◆ **Outsole** is the material on the bottom of the shoe that comes in direct contact with the running surface.
- ◆ **Midsole** is the layer of cushioning that is placed between the upper and outsoles.
- ◆ **Lateral** is the outer-edge of the shoe.
- ◆ **Medial** is the inner or arch side of the shoe.
- ◆ **Upper** is the part of the sole that is above the midsole.
- ◆ **Achilles notch** is the U or V-shaped cut at the top of the heel collar which prevents irritation of the achilles tendon.
- ◆ **Heel counter** is a firm cup usually made of plastic that is encased in the upper and surrounds the heel to control excessive rear foot motion.
- ◆ **External heel counter** is a rigid plastic collar that wraps around the heel of the shoe to provide support and control excess pronation.
- ◆ **Motion control designs** or devices control the inward rolling or pronation of the foot. Some amount of pronation is normal: corrective measures are necessary only if there is excessive rolling or under-pronation.

Terms Related to Cushioning

- ◆ **Cushioning** is provided by midsoles and is needed for shock absorption.

- ◆ **Cantilever** is a concave outsole design in which the outer edges flare out during foot strike to provide better shock absorption.
- ◆ **EVA** is a foam-like material which is used in midsoles to provide cushioning.
- ◆ **Polyurethane (PU)** is a synthetic rubber that is used with EVA in midsoles. It is more durable than EVA but provides less cushioning. PU is used in the rear foot for firmness and EVA in the forefoot for flexibility and lightness in many shoe models.
- ◆ **Metatarsal pad** is a soft wedge of EVA that is placed under the ball of the foot to increase cushioning and shock absorption for runners who are fore-foot strikers.

Terms Related to Shape

- ◆ **Last** is a foot shaped piece of wood, plastic or metal which is used as a frame for building a shoe. Lasts can be straight or curved as shown in Figure 4-2.
- ◆ **Straight-lasted shoes** are relatively straight shaped on the inner or medial side and provide support and stability and are recommended for runners who over-pronate.
- ◆ **Curve-lasted shoes** are shaped to curve inwards (see figure). This shape allows greater foot motion and such shoes can be worn by runners with normal pronation and arches.

Straight Curve

Figure 4-2. Types of Lasts Used for Running Shoes

Terms Related to Shoe Construction

- ◆ **Board lasting** increases stability and is good for orthotics. A board-lasted shoe is made by gluing the upper to fiber board before it is attached to the midsole.
- ◆ **Slip lasting** is the most flexible shoe construction wherein the shoe upper is stitched together like a moccasin before it is glued to the midsole.
- ◆ **Combination lasting** as the term suggests is partly board and partly slip lasting. Such shoes are board lasted in the rear foot for stability and slip lasted in the fore-foot for greater flexibility. If you removed the sockliner you would see stitching in front and a fiber-board in the rear foot.

Figure 4-3. Shoe Construction: Lasting

Pointers for Buying Running Shoes

- ◆ Maximum emphasis on shock-absorbing characteristics.
- ◆ Know your foot type.
- ◆ Look for shoes that come in widths.

Do you have normal arches, high arches or are you flat footed? You can assess your foot type by what is known as the “wet test”: simply wet your feet and briefly stand on a piece of paper or on a dark, bare floor; look at the imprint left by your feet. Compare them to the impressions shown in Figure 4-4 to determine your foot type.

Figure 4-4. Types of Arches

If you have high arches you will need a shoe with more cushioning for shock absorption whereas if you are flat footed you will need a shoe with more support and heel control (see Table 4-1).

◆ **Know whether you over- or under-pronate.**

If you over-pronate you need shoes that provide stability, whereas, if you under-pronate you need shoes that provide shock absorption and cushioning.

◆ **Know if you are prone to running injuries.**

See a sports medicine doctor if you are predisposed to training/overuse injuries to determine if your injuries are related to biomechanics. Biomechanical conditions, such as being an over- or under-pronator, or having one leg shorter than the other, often result in running injuries. In some cases, you may benefit from using orthotics (see section on orthotics) in your running shoes. Also, take your running shoes with you when you go to see your doctor.

◆ **Try on shoes towards the end of the day.**

Feet are smallest first thing in the morning and swell slightly as the day progresses. Also, wear running or sports socks while trying on shoes since they are generally thicker than regular socks. Walk around the store in the shoes to check the fit, cushioning and stability of the shoe. If you use orthotics, lifts or other inserts, bring them with you when you try on shoes.

◆ **Do not buy shoes based on their brand name.**

Buy shoes that suit your biomechanical needs and work for your foot type, not shoes that a friend highly recommended or shoes you have seen a “good” runner wear. Consider going to a specialty shoe store where a knowledgeable salesperson can evaluate your running style and biomechanical needs, and recommend a shoe.

◆ **Replace worn out shoes in a timely manner.**

Wearing worn out shoes can eventually lead to injuries and cause knee or hip pain. It is a good idea to replace running shoes every 400 to 500 miles, or sooner if your shoes wear down quickly. One way to keep track of your running mileage is to establish a running log. A running log will not only help in keeping track of your running distance, but it will also help in tracking factors such as sudden increases in mileage or the onset of injury.

Table 4-1. The Right Shoe for Your Foot Type

Shoe Features	Flat Feet	Normal Feet	High-Arched Feet
Last - Shape	Straight	Semi-curved	Curved
Last - Construction	Combination	Combination	Slip
Midsole	Firm	Soft or firm	Soft
Motion Control	Yes	No	No
Orthotic Sole	May be needed to correct for over-pronation	No	No
External Heel Counter	Yes	No	Yes
Recommended Shoe Type	Motion control or stability shoes with firm mid-soles	Stability shoes with moderate control features such as two-density mid-sole	Cushioned shoes to provide lots of flexibility and promote foot motion
Avoid	Highly cushioned and curve-lasted shoes		Motion control or stability shoes

Orthotics

Individuals with biomechanical conditions that result in pain and injury may benefit from using orthotics in their running shoes. Orthotics are shoe inserts that are customized to an individual's biomechanics and foot type to provide good foot support and motion control. First, a plaster mold of the foot is made and then inserts are developed to correct the biomechanical problem(s). These inserts are usually made of cork soles covered by flexible leather or hard plastic. Orthotics should be gradually broken in; first wear them while walking and then progress to running. If not properly fitted, orthotics may worsen the problem. A podiatrist or sports medicine specialist is required to have them custom-made.

Sometimes low cost, over-the-counter, commercial orthotic inserts can work as well as customized inserts. For example, if the amount of pronation is not too much, over-the-counter inserts may correct the problem. Commercial inserts are sold by shoe size. If you find that the pain lessens, but does not go away or that the pain returns when you increase your mileage, you may need custom-made orthotics.

Cleats for Cold Weather Running

By putting on rubber cleats over a pair of running shoes you will be able to run outdoors under icy conditions. Personnel in the Arctic Warrior Brigade in Alaska use cleats when training in frigid weather. To obtain information about ordering these cleats, call Ft. Wainright (DSN 317-353-6048).

Clothes

Unlike many sports, running is not seasonal and with the right clothes, it is possible to continue to train outdoors on very hot or very cold days (see Chapter 11: Special Considerations for Training to review training under adverse environmental conditions). When weather conditions are extreme, as in ice storms, blizzards or a major heat wave, outdoor training can be substituted with running on a treadmill in the gym. Thus, running clothes can range from a simple pair of running shorts and a singlet to running tights and gortex jackets, depending on environmental temperatures. Cold weather running requires dressing in layers. Always keep your head and extremities warm in cold weather. Experience will teach you what to wear when running in the cold. If you wear too much, you may get hot after warming up, i.e., within the first mile or so.

Running socks tend to cost a bit more, but they are thicker and provide more cushioning than average sports socks. In most cases, sports socks are recommended as they provide adequate cushioning.

Other Gear Items

Heart Rate Monitors

You may have seen these advertised in running and fitness magazines. Some athletes use these for monitoring their training intensities. Such monitors consist of a wrist watch and a chest strap: the chest strap has an electrode which picks up your heart beat and transmits it to the watch which in turn displays your heart rate in beats per minute. If you know your target training zone (see Chapter 1) you can check and maintain your heart rate within that zone. Heart rate monitors are not a training necessity and can be expensive.

Reflectors

Putting reflectors on your shoes and running clothes is a great idea if you routinely run late in the evening, at night, or very early in the morning when visibility is particularly poor. This is especially important in urban areas where motorists may not be paying particular attention to runners. Note that you should also run against the traffic.

Fluid Containers that Strap onto Belts

As you already know, it is very important to maintain fluid balance and prevent dehydration. Thus, if your long runs include running for more than 90 minutes, especially in hot weather, it is advisable to strap on a fluid container and drink fluid (8 oz.) at 30 minute intervals (refer to *The Navy SEAL Nutrition Guide*). If your running route provides access to water fountains then you need not carry your own fluid supply.

Portable Radio/Cassette Player/Walkman

Running with headphones can really help during long runs. However, it is not advisable to wear headphones and run on city streets as it may reduce your awareness of your surroundings. Running with headphones on base may be prohibited.

Running Surfaces

The ideal running surface is flat, firm, smooth and provides some shock absorption. Surfaces in the order of most to least desirable are listed in Table 4-2.

Table 4-2. Running Surfaces: From Best to Worst

Surface	Comment	Rating
Soft, smooth cinder track, unbanked	Least likely of all to aggravate biomechanical injuries. Change direction frequently on any track to reduce mechanical problems.	1- Best
Artificially surfaced track, unbanked	Provides less shock absorption than the cinder track.	2
Soft, smooth dirt trail	Provides reasonable cushioning and holes and ruts are clearly visible.	3

Table 4-2. Running Surfaces: From Best to Worst

Surface	Comment	Rating
Flat, smooth grass	Grassy areas including golf courses make relatively poor running surfaces since they hide uneven areas.	4
Asphalt street or path	Poor surfaces since typically sloped to facilitate rain water run-off. Surface slant causes one foot to pronate more and other to supinate more. Biomechanical problems are aggravated especially if runner tends to run in the same direction each time. Changing directions is highly recommended.	5
Hard, dirt track or trail	Watch out for ruts, holes, loose stones.	6
Concrete sidewalk or road	A very hard surface: wear good shock absorbing shoes.	7
Banked or cambered surface	Severe incline puts stress on the knees.	8
Hard-sand or soft sand beach	Beaches are slanted and can aggravate biomechanical problems. Do not run barefoot.	9
Rough, pot-holed, dirt trail or grass	A particularly hazardous surface. An unexpected hole or rut can result in ankle sprains.	10 - worst

Source: *Running Injury-Free* by Joe Ellis with Joe Henderson, Rodale Press, 1994

Other running surfaces include treadmills and water. Treadmills are very popular at fitness centers and may also be available to you when deployed aboard a ship. Most treadmills are state of the art in terms of cushioning and you can control the speed and intensity of your work out. Perhaps the biggest problem when working out on a treadmill is the boredom that is often associated with the monotony of the unchanging environment and the consistent pace. A portable cassette player or radio may be helpful, particularly during longer runs.

Deep water or aqua running is mainly used for rehabilitating injured athletes as it takes the pressure off of injured muscles and joints while providing cardiovascular benefits similar to those obtained with running on surface. This type of running is becoming popular at various swim centers.

Warm-Up

A warm-up to lengthen short, tight muscles before running is crucial for preventing injuries that may result if muscles are “cold”. A longer muscle is less likely to get injured than a short, tight muscle because it can exert more force with less effort than a short muscle. Another benefit of warming up is that it protects tendons. Warm up by slow jogging or walking for five to 10 minutes before you run. **After you warm up you need to stretch your hamstrings, quadriceps, hip flexors, groin, calves, achilles, and the iliotibial band.** Exercises to accomplish these stretches are provided in the chapters on “Flexibility” and “Calisthenics” and are included in your recommended PT (Chapter 15).

Cool-Down and Stretching

After completing your run, walk for a few minutes to cool-down. It is not a good idea to sprint at the end of your run and then come to a complete stop; this practice may result in an injury. Cooling down helps to shift the blood flow from the muscles to the heart and other vital organs. A cool down lets your heart rate slow down and your body gradually return to its pre-exercise physiological state. **Cooling down properly and stretching (see Chapter 7: Flexibility) after your run will go a long way towards preventing injuries.**

Running Gait or Form

Different runners may have different running styles. Running is a function of footstrike, forward stride, body angle, and arm drive. The key is:

Run naturally and remain relaxed.

Footstrike

For most runners, other than sprinters or very fast runners, the heel-ball footstrike method works well: (1) the outside of the heel strikes the surface; (2) the foot rolls inwards to the ball of the foot while the knee is slightly bent; and (3) the foot lifts off from propulsion provided by the big toe. This method provides good shock absorption.

Forward Stride

The point of foot contact should occur in line with the knee which should be slightly flexed. As you improve and get faster, the length and frequency of your strides will increase and you will begin lifting your knees higher. Do not overstride such that your foot hits the ground ahead of the knee flex (i.e. leg should not be straight at point of impact). Overstriding is hard on the knees, back and the hips and can cause injuries. Short, choppy strides, which usually result from tight or inflexible muscles, require more energy and are inefficient. Run with a relaxed stride and do not exaggerate the knee-lift or back kick.

Body Angle

Keep your back as straight as naturally possible, your head up and look ahead. Of course, depending on the terrain you may have to look down to avoid tripping or landing in a hole or rut. Lean forward only when going uphill or sprinting as this motion will put stress on leg muscles and may cause back pain and shin splints. Leaning back is not recommended as this puts tremendous pressure on the back and legs and has a “braking effect”. The key is to run “tall” and remain relaxed; allow your shoulders to hang in a relaxed manner and let your arms drop from time to time.

Arm Drive

While running relax your shoulders, elbows, wrists and fists and occasionally let your arms hang down at your sides and loosely shake them out. Whereas vigorous pumping of the arms helps sprinters, it is unnecessary during distance running.

Building Your Mileage

Increasing mileage too quickly can cause training injuries. Your running mileage should be gradually increased and not by more than 10% to 20% from one week to the next. For example, if you can comfortably run four miles, increase your distance by a mile and maintain this new mileage for at least one to two weeks or until this distance is consistently easy for you. Also, remember consistency is more important than speed.

A good rule of thumb: increase your mileage by no more than 20% a week.

When you can continuously run for 40 minutes, begin thinking about your running mileage or distance. Most of you, unless coming back from an injury or returning from a deployment, are already running 30 to 40 minutes as part of your fitness routine. However, if you have been unable to run for some time due to reasons mentioned above or other reasons, start out slowly; this will prevent you from getting injured and benefit you in the long run.

Running Frequency

Run at least three to four times per week or every other day. It is a good idea to build in one or two rest days in your weekly running schedule. These rest days do not necessarily mean no exercise, but rather an alternate type of exercise, such as biking or swimming. This allows your “running muscles” time for rest and recovery, and helps prevent overuse training injuries.

Running Speed and Intensity

When running for exercise and not competition, you should run at an even pace that allows you to talk comfortably. If you run too fast and get breathless, you may not be able to go the distance. Also, speed work tends to tighten muscles and must be properly stretched afterwards. Failure to stretch may lead to an injury. One way to estimate your training intensity is to check your heart rate and see if it falls within your target training zone (See Chapter 1). As previously mentioned, speed is not as important as being able to go the distance consistently. Figure 4-5 presents tips on how to increase your running speed.

Figure 4-5. Ways to Increase Running Speed

Increase length of stride: do not overstride
Increase frequency of stride
Increase length and frequency of stride

Do not increase speed and distance simultaneously.

Increasing both at the same time may cause an injury. Hold one constant while you gradually increase the other. After you have been running 30 minutes continuously 3 - 5 times per week, you can begin increasing your running distance. Running 20 to 30 miles per week is a good training distance for an intermediate runner. If you would like to further increase your weekly mileage, remember to increase it by no more than 20% per week. Table 4-3 provides a nine week program for running up to 40 miles per week.

Table 4-3. A Program to Run 40 Miles per Week

Week	Mon	Tues	Wed	Thur	Fri	Sat	Sun	Total
One	4	CT*	5	3	CT	3	5	20
Three	5	CT	5	5	CT	5	5	24
Five	5	CT	6	6	CT	6	6	29
Seven	7	CT	7	8	CT	5	8	35
Nine	6	CT	8	8	CT	8	10	40

*CT=Cross train on these days.

The program in Table 4-3 provides a basic template for you. Based on your own routine, you could modify this program to fit your schedule and requirements. Another way to vary your workout is to have one long slow run and one fast run per week. Remember if you feel over tired, cut back your mileage or take a day off from running. With a running base of 40 miles per week you can easily run a half marathon.

Training for a Marathon

If you have been running 35 to 40 miles per week for 1 to 2 months, you have a good endurance base for running a marathon after 3 additional months (12 weeks) of training (Table 4-4). To run a marathon, you must complete some long training runs in the weeks leading up to the marathon. The week that you run the marathon, however, should include only a few short runs. Your goal for your first marathon should be to complete it.

Table 4-4. A 12 Week Marathon Training Program Starting at 40 Miles/Week

Week	Mon	Tues	Wed	Thur	Fri	Sat	Sun	Total
One	-	5	8	5	5	4	15	42
Two	-	8	5	10	5	5	12	45
Three	-	6	8	6	6	4	15	45
Four	-	8	8	10	5	5	14	50
Five	-	6	8	8	6	4	18	50
Six	-	6	10	12	5	8	14	55
Seven	-	5	10	10	6	4	20	55
Eight	-	8	10	10	10	8	14	60
Nine	-	8	10	10	6	6	20	60
Ten	-	8	4	10	10	8	15	55
Eleven	-	5	10	10	5	4	18	55
Twelve	-	8	6	4	-	2	Marathon	

Other Points to Consider

- ◆ Make sure you eat enough carbohydrates and are well hydrated before the marathon. Refer to *The Navy SEAL Nutrition Guide* for information about high carbohydrate diets and fluid replacement beverages.
- ◆ Start out slowly and pace yourself.
- ◆ Walk for a while if you get cramps or feel fatigued.
- ◆ Consider the environmental temperature; if it is a hot and humid day, it is especially important to pay attention to your fluid and electrolyte needs (Refer to Chapter 11 and to *The Navy SEAL Nutrition Guide*).

- ◆ After you finish, stretch and walk around. Take a hot bath.
- ◆ Slowly return to running.

Interval Training

Various interval training techniques can be used for building speed. Ideally, speed work would be done on a measured track. Sample interval training workouts are provided in Figure 4-6. Two important points are:

- ◆ Rest periods between reps for intervals to train the anaerobic energy systems should be equal or slightly less than time to cover distance (quarter mile: 60 seconds; rest: 60 seconds).
- ◆ Rest periods to train aerobic system should be less than one-half time to cover distance (half-mile: 2:50; rest: 60 seconds).

Figure 4-6. Sample Sprint and Distance Running Interval Workouts

Sprint

One mile warm-up, slow pace
10 minutes lower body stretching
Quarter mile sprint w/ 60 to 90 second jogs: Repeat five times
Half mile sprints/ 2 to 3 minutes jogs: Repeat three times
One mile cool-down, easy pace
Whole body stretching

Distance

One mile warm-up, slow pace
10 minutes lower body stretching
One mile sprints/ 1 to 2 minute jogs: Repeat four times
Two mile cool-down, easy pace
Whole body stretching

These are not the only interval workouts, so you may modify them to suit your requirements. For example, you could do pyramids: you would start with a quarter mile, followed by a half mile, 3/4 mile, and mile, then go back down in reverse. Between each speed set, it is best to jog one quarter to one half the distance to accelerate recovery.

Interval workouts are a great way to improve performance.

Varying Your Workouts

It is good idea to vary your daily running mileage so you have some “light” days in between heavy training. Avoid running long distances on two consecutive days, unless you are training for a marathon, to give your body time to recover. Listen to your body and pace yourself accordingly.

**Most importantly,
it is good to cross-train.**

Consider biking, swimming, stair-climbing or other activities that will provide a good aerobic workout while mainly using muscles other than those used during running. A major benefit of cross training is that it prevents the onset of over-use injuries while maintaining fitness. For information about cross-training see Chapter 3: Cardiorespiratory Conditioning. Strength training, especially upper body strength workouts, have become an important part of a “runner’s” overall workout. It is recommended that you strength train two to three times a week (see Chapter 6).

Common Running Injuries or Problems

Most running injuries are due to “over use” from running too much, i.e. too fast, too far, or too often. See Chapter 12: Training and Sports Related Injuries for more information about injuries. The following table shows the incidence of various running injuries that were reported by male runners in a recent survey (Adapted from *Running Injury-Free* By Joe Ellis with Joe Henderson, Rodale Press, 1994).

Table 4-5. Frequency of Running Injuries Reported by a Sample of Male Runners

Injury	Frequency (%)
Knee	23
Achilles Tendon/Calf	16
Metatarsal	11
Hip/Groin/Toenails/Blisters	9
Plantar Fascia/Heel	8
Ankle Sprain	7
Shin Splints	6
Nerve/Quadriceps/Hamstring/Back	2

If you train sensibly there is no reason why you should not be able run injury-free. Should you get injured, information on how to go about seeking treatment for training related injuries is provided in Chapter 12. Keep in mind the three principles of a good running form as shown in Table 4-6.

Table 4-6. Three “Principles” of Good Running Form

Run Tall
Run Relaxed
Run Naturally

Chapter 5

Swimming for Fitness

As a SEAL you are required to be a swimmer. Swimming is an excellent exercise for overall fitness; aerobic endurance, power, strength, and flexibility are all enhanced by swim training. It is generally gentle on the joints and provides excellent cross training for running and other gravity-intensive forms of exercise by providing load-bearing joint rest. However, training must be specific for the anticipated operational environment, including cold water acclimatization. This section will give you the tools to improve your swimming skills, thus enhancing your fitness for combat swimmer missions.

You must primarily train for endurance while preserving the significant power and strength required by other phases of SEAL operations. This section includes information on competitive swimming strokes and pool training, but it is important to emphasize that most training for SEAL combat swimmer operations should consist of open water swims with fins. Open water training is essential for SEALs as a part of a comprehensive training program under the general principle of “specificity of training”. Surf and high sea state swimming provides specific training for potential operational situations by increasing your sense of timing and confidence.

Swim training should focus primarily on open water swims with fins.

Swim training is best accomplished with others for a variety of safety reasons. There should always be a guard or buddy available to you, even if you swim in a pool. You certainly should not train alone in open water.

Open Water Gear

In the pure sense the only gear required is a set of trunks. Look at the gear list for the UDT swimmers at Omaha Beach in 1944. It did not even include fins and masks. However, today there are some significant gear issues. Goggles are necessary for any real swim training. Operational and open water swimming requires more gear. There are specific training aids that help develop strength and technique in pool training. Swimming is still an inexpensive sport with respect to gear; a complete set of the most expensive training gear for pool training will not cost over \$100.

Wet Suits

Open water swimming may require thermal protection for safety. Males in particular may be susceptible to hypothermia and the first symptom in an open water swimmer may be unconsciousness from cardiac arrhythmia. Thermal protection in swimmers means a wet suit worn over an anti-chafing shirt.

Wet suits designed for open water swimming are generally of a Farmer John design with the arms free for stroking. In all but the coldest water, a 1/8" wet suit is best for surface swimming. Unlike diving, there is no need to factor in the loss of insulation due to compression of the neoprene with depth. However, this is not true for the combat swimmer operations that may entail prolonged periods in the water.

Anti-chafing shirts are generally made of nylon without elastic properties. Worn under the wet suit, the nylon shirt allows arm strokes and head rotation without getting chafing from the wet suit. If you don't use anti-chafe shirts, then this would not matter.

Hood, Gloves and Booties

- ◆ Good open water swimming hoods allow the head to be turned with minimal chafing. Thermal protection is not as good with the neck exposed. A good hood preserves a great deal of the swimmer's heat.
- ◆ Gloves may have webbed fingers to allow sidestroke pulling to be more efficient. They work great for freestyle, too. Neoprene web gloves are popular and work like paddles.
- ◆ Thin 1/8" booties without soles maximize the power delivered by the swimmer's legs to the fins.

Fins and Fin Selection

There are three factors to keep in mind when you are selecting a fin; the specific design characteristics of the fin, the physical attributes particular to your body, and operational constraints. Fins, by increasing the surface area of the foot, serve to magnify the thrust delivered by the legs. Kicking with fins involves a forward stroke and a backward stroke. Several examples will illustrate how the three factors interact to influence the SEAL's fin selection.

- ◆ SDV operations require an operator to sit with fins on for a long period of time. The operator may require thermal protection and he may have a flexible ankle. Space is limited, so a shorter fin is necessary. For this situation, the operator should select a short, wide fin with a strap that can be adjusted for varying amounts of thermal wear.
- ◆ Surface swimming with gear will involve a sidestroke flutterkick. In the sidestroke, forward is toward the front of the swimmer's body and backward is toward the swimmer's back. Applied force is typically much greater during the forward stroke, and fins are often designed with this fact in mind. When power is needed for both forward and backward kick, like in sidestroke, a straight symmetrical fin may be more efficient for you.
- ◆ Underwater swimming involves a face down position, where the forward stroke is down and the backward stroke is up towards the surface of the water. In this position, gravity assists with the downstroke and produces a less symmetrical type of thrust than seen with sidestroke kick. You should select a high-tech diving fin with moderate flexibility and an integral type footbox. The fin should have an offset design to allow a more efficient transfer of propulsion force.
- ◆ For bodysurfing, use short surf fins.

The main principle of fins is to increase the surface area of the foot.

Table 5-1. Recommended Fin Types

Type of Swimming	Type of Fin
SDV Operation	Short fin (Beware of compromised propulsion power. Rocket fin is wide and may provide extra safety factor).
Underwater Swimming	Offset fin
Surface Swimming	Straight fin

Figure 5-1. Examples of Traditional Short and Long Fins (Left) and Newer Long Blade Fins with Innovative Buckles (Right)

Specific Design Characteristics of Fins:

- ◆ Size or surface area of fin blade.
- ◆ Stiffness of fin blade.
- ◆ Configuration or shape of fin blade - length and width.
- ◆ Integral footbox versus strap-type fin.
- ◆ “Offset” or angle of pitch between footbox and fin blade.
- ◆ Buoyancy of fin.

Physical Attributes Influencing Fin Selection:

- ◆ If your ankle range of motion is inherently limited, long fins will assist in transmitting lower extremity forces to the water.

- ◆ If your ankles are inherently flexible, short fins may be more efficient as well as less stressful on relaxed ankle joints.
- ◆ Your natural kick frequency will also influence your choice of fin stiffness and size. Larger sizes and stiffness produces a slower rate of kicking, while short flexible fins allow a higher kick rate.

Operational Constraints:

- ◆ Face down versus sidestroke position.
- ◆ Surface versus submerged.
- ◆ Space limitations (SDV).
- ◆ Thermal protection.

The fit of the fin is critical.

If the fin is too tight, the finbox may make your foot cramp up and more susceptible to cold. If it is too loose, energy is lost in the slop between foot and footbox; slop also translates into foot chafe! Booties provide grip for the foot within the footbox and the neoprene acts to even out areas where stress is concentrated.

Other Fin Selection Considerations

Fins vary slightly in buoyancy; about half of sport fin models float and the remainder sink. This may be an operational consideration. In the April 1996 Rodale's Scuba Diving fin test, fins testing as "outstanding" in the area of power included the expensive Scubapro Gorilla, Mares/Plana Avanti, Ocean Edge Spectra, and the U.S. Divers Blades. However, so did the IDI Frog Foot and Power Fin models, which have been the standard fins in the Teams for many years.

The authors of the article reveal honestly that, "In spite of extensive research and a multiplicity of designs applied to modern fins, there are still tried and true fins that perform as well as many of the top newer models." The older, buckle-style strap fasteners have the advantage of being reversible and are far less likely to foul in fishing line or seaweed than fasteners on newer models, many of which have quick-release buckles. The simple straps on older models have no plastic to break, are easy and inexpensive to replace, and can be found in almost any dive store. These fins are also not as slippery on deck as newer designs.

As a SEAL, you will need to evaluate individual fin performance carefully. You should not only consider characteristics of the fin, but know your own physical attributes and any particular operational constraints in making your decision.

When buying fins consider:

- ◆ Size, stiffness, weight, buoyancy, buckles and releases.

- ◆ Getting the best possible fit; try on fins with booties or other foot gear that you'll be using with the fins.

Face Masks

A face-mask is required for swimming as prolonged exposure to salt water and/or stinging marine organisms may cause eye irritation or injury.

**For open water swimming, you
should
use your face masks.**

Open Water Training

There is no substitute for ocean or lake swimming. Training in open water will force you to swim straight and develop a cycle of breathing that allows you to look forward in order to navigate. This is an essential skill for operational swimming. Group swims in open water are an excellent way to maintain fitness and should be used extensively in SEAL training programs. Open water training will maximize the training effect of using fins.

**For operational open water swimming,
the sidestroke with a flutterkick
is superior to freestyle.**

In rough open water and under operational circumstances you may want to combine a scissor kick with a sidestroke pulling technique to maximize your navigational ability and watch for breaking waves. However, sculling is as important in the sidestroke as it is in freestyle. Both arms should be used to incorporate sculling motions and to stabilize the swimmer's trunk while the kick provides the main thrust. There are stroke efficiency issues with the sidestroke just as there are in other swimming strokes. Stroke coaching is invaluable in developing good technique.

Water Temperature Issues

Cold water is an issue to be addressed by SEALs training in open water. Although the work of swimming generates heat, there is heat loss created by movement of the swimmer into new “unheated” cold water. Thus, open water swimming may require various combinations of passive thermal protective gear, in particular, wet suits. The three determinants for passive thermal protection are:

- ◆ Temperature
- ◆ Length of the swim
- ◆ Effort level

It is important to remember that wet suits operate by allowing the body heat to be transferred to a layer of water caught between the body and the neoprene material of the suit. Convective heat loss from the swimmer's body is greatly reduced by this mechanism and as a result, swimming at a high effort while wearing a wet suit allows the swimmer to generate and retain heat. Guidelines have been developed for training and are presented in this section.

Research has established some known “bench mark” facts about operating in a cold water environment. In very cold water (below 40° F), the unprotected swimmer loses heat faster than an immobile person immersed in the same cold water. Heat generation simply does not keep up with losses. The immobile person warms the cold water immediately around his body thereby limiting total heat loss. However, in moderately cold water (around 68° F), an elite class swimmer may stay active, and the heat generated by swimming keeps pace with overall losses (although the swimmer may develop cold feet and hands). In this situation, the active swimmer outperforms the immobile person with respect to maintenance of core body temperature. Currently we do not know the crossover temperature point or the water temperature at which it is better to remain stationary than active in the water for thermal balance.

Passive thermal protection modifies this balance by reducing the convective component of heat loss. As a result, a swimmer may extend training durations beyond those possible without passive thermal protection. Diving medicine specialists at BUDS have

developed guidelines for use of passive thermal protection during training in cold water environments. Note that Table 5-2 is limited to high energy swims at a set distance of 2 miles.

Table 5-2. Distance, Temperature, and Protection Requirements

Swim	Water Temperature (°F)	Protection
Swim of 2 miles	> 64°	None
	63 - 64°	Hood Only
	60 - 62°	Wet-Suit Top/Hood
	50 - 60°	Full Wet Suit/Hood

Special Open Water Training Issues

It is easy to have chafing from the wet suit around the arms and also for the fins to chafe. Get thin booties without soles for fin use and consider using some vaseline or aquaphor ointment for other chafe points.

If you swim regularly in cold water, your body will undergo some adaptive changes. This will increase your tolerance to some extent. You will also begin to actually crave fatty foods, an instinctual tendency of cold water swimmers to want extra body fat to protect them! This is a natural adaptation, but this may be undesirable for your running and overall fitness.

Surf training is great for honing your aquatic skills and for developing confidence in big water. For body-surfing, use a medium fin, like short surfing fins, that permits quick acceleration but is small enough not to get caught in moving parts of the wave. Use velcro-elastic “keepers” for your fins unless you are sponsored by a fin manufacturer!

Keep your head down and always surf with an arm extended up over your head.

It is far better if you get folded by a big chopping wave to have your shoulder dislocated than for you to become quadriplegic from a cervical spine injury. Avoid shorebreaks; the waves are unpredictable and going over the falls may yield a screaming descent straight onto the beach sand. Instead try to find a good “grab and release” break where the wave stands up nicely and then breaks back into deeper water.

Another open water issue you may be faced with is that of sharks. They commonly attack solitary swimmers, particularly freestylers: the solitary, beefy organism making arm slaps against the surface of the water. Avoid swimming in places where you may resemble part of the food chain, but even then there appears to be protection in numbers. A good example is La Jolla Cove near San Diego. Here triathletes swim and Great White sharks eat small mammals all in the same day. Avoid swimming in the evening and get out of the ocean if you get bloodied too much in the surf.

Sharks virtually never attack swimmers in groups.

Swimming Pool Gear

Goggles

The most important gear for pool training is a good set of goggles. Get goggles that can be adjusted across the bridge of the nose. The fog-free goggles work better than they used to, but they do lose this quality relatively quickly under hard use and are much more expensive.

Kickboard

A kickboard is essential. They come in a wide variety of sizes and shapes, but all do basically the same thing.

Pullbuoy

A cheap, but essential, piece of training gear, the pullbuoy fits between the swimmer's legs for specific types of swim drills.

Hand Paddles

These are useful to develop the feel of sculling during freestyle pulling.

Zoomers

A unique and expensive short fin, the Zoomer is helpful but not essential. This special fin is designed to allow the swimmer to use flip turns during pool training sessions with minimal interference with technique. Other short fins may be substituted, notably the short, surf fins.

Nose Clips

Many individuals develop low grade nasal reaction to pool water. Use of a nose clip will allow a swimmer to complete some of the backstroke drills presented in this chapter much more comfortably.

Pool Training: Building Strength and Endurance

The major reason to use a pool is the quality of training. Swim sessions may be closely monitored and are safe. Controlled interval workouts used in pool training sessions provide good feedback; the pace clock doesn't lie. Pool sessions allow you to design workouts that vary in intensity and emphasis, which is not possible in open water. Pool training and acquisition of improved stroke skills are elective elements of a SEAL's training program. Pool training will increase your comfort level in open water, thus enabling you to significantly improve your operational capabilities.

Swimming is not an intuitive activity like running.

Warming Up

Warming-up should consist of at least 400 meters of swimming, along with some kicking and pulling drills. Warming-up is essential for swimming to avoid developing problems of the shoulder joint and upper back.

Target heart rate during warm-up should be about 60% of maximal.

During your warm-up, work on efficient stroke “stealth” swimming! Warming-up is an appropriate time to include stroke drills. This serves the purpose of providing stroke patterning along with the warm-up.

Basic Principles of Interval Training

SEALs need to concentrate on swim training that will enhance endurance: interval swim training will allow this to happen. Interval training sets (for both strength and endurance) are generally comprised of repeated swims lasting 45 seconds to 4 minutes. Basics of interval training include the following:

- ◆ Swim at a slow to moderate pace for five to ten minutes to warm-up muscles and cardiorespiratory system.
- ◆ For anaerobic training, sets should be performed until repeat times can no longer be held. There is no magical number of repetitions for a set, but the distance is typically 50 to 100 meters, or a time of about 45 seconds.
- ◆ Swimming at a prescribed intensity pace for as long as possible is most important. When desired pace can no longer be sustained, the set should be terminated.
- ◆ Work:recovery ratios play an important part in the type of adaptation that occurs. A 1:1 work:recovery ratio would be to swim 45 seconds and rest 45 seconds, whereas a 1:2 ratio would be to swim 45 seconds and rest 90 seconds.
- ◆ To stimulate endurance adaptations, recovery intervals between repetitions should be less than 30 seconds. For maximum benefit, it is best to keep the interval less than 15 seconds.
- ◆ For anaerobic adaptations to occur, recovery intervals should be in excess of one minute and up to at least twice the duration of the repetition swim. These effects occur independent of the repetition distance or pace.
- ◆ The longer the rest interval, irrespective of the distance being repeated, the greater the use of the anaerobic system. With long rests, it takes considerably longer for the aerobic energy system to be reactivated. Short rest intervals keep the aerobic system functioning, particularly during initial recovery.

Interval training is the backbone of a swimming workout.

Figure 5-2 illustrates how the different energy systems can be trained in an interval workout. Swim 1 is a hard effort, short distance and a lot of rest; this type of effort builds the anaerobic (CP) and transitional (Lactate-CP) energy systems. The second swim consists of fewer sets at a longer distance and with shorter rest intervals; this swim would challenge the aerobic system.

Figure 5-2. Energy Systems Used During Interval Sets

Lactate-CP System

Swim 1: 10 X 100 m with 45 sec. rest

10 = Repetitions (Sets)

100 m = Distance in Meters

Aerobic System

Swim 2: 5 X 200 m with 5 sec. rest

5 = Repetitions (Sets)

200 m = Distance in Meters

A swimming pace clock is the best way to time intervals: a diving watch works fine.

Interval Sets - Endurance

Freestyle Swim: 10 x 50 m with only 5 sec. rest

- ◆ Rest 5 seconds between each swim.
- ◆ Start with efficient “stealth” stroke, work into distance race pace. Don't over-kick.
- ◆ Try to match your 1000 meter pace with this set.

Freestyle Swim: 50-50-100 m with 5 sec. rest

- ◆ Swim 2 x 50 meters with 5 seconds rest, then swim 100 meters: Repeat 3X.
- ◆ This set builds into a 100 meter swim where the swimmer tries to match the pace set in the 50 meters.
- ◆ Back off of the 50 meters a little to save up for the 100 meters.
- ◆ If you want, add an extra 15 seconds of rest between each 50-50-100 to keep the quality up.
- ◆ A “buildup” set like this will do great things for your endurance and sense of pace.

Freestyle Swim: 10 x 100 m with 10 sec. rest

- ◆ Rest 10 seconds between each 100 meter swim.
- ◆ Swim smoothly and efficiently. This is the set where you may exceed your long, slow swimming 1000 meter time!

Breaststroke Swim: 50-50-100 m - 5 sec. rest

- ◆ Done like the freestyle 50-50-100 set outlined above.
- ◆ Concentrate on keeping effort level up.

Interval Sets - Strength and Power

Freestyle Swim: 10 x 50 m with 30 sec. rest

- ◆ Begin at a strong pace. Build to race pace with a strong turn and an extra strong finish. Try to be within 5 seconds of your race 50 meters pace, usually equal to your race 200 meter pace.
- ◆ At first, try just 5 x 50 meters with 30 second rest.
- ◆ This is the most power-oriented freestyle set. It will also allow you to discover your true maximal heart rate. If you start to die off at the end, increase your rest a little to keep your pace.
- ◆ If you are particularly strong and want to build more speed, do this set with zoomers.

Freestyle Swim: 10 x 100 m with 45 sec. rest

- ◆ Same pace approach as the 50 meter interval set. This is for advanced swimmers with a refined stroke. It will build power, but this set should be used no more than once every two weeks.
- ◆ The rest interval should be 45 seconds for this length of swim; adjust your interval accordingly.

Breaststroke Swim: 10 x 50 m with 30 sec. rest

- ◆ Like backstroke, work on hard swimming with about 30 seconds of rest. Breaststroke is very taxing when done hard but like bicycling it is easy to throttle back and have the appearance without the substance.

Integrated Workouts

For pool training it is necessary to integrate your sets into a comprehensive workout. At first you will want to limit your hard sets, but as your fitness improves, hard drills can be extended. It also worthwhile alternating between anaerobic and aerobic workouts. In this way your performance for combat swimmer operations should be optimized.

**Figure 5-3. Sample Anaerobic and Aerobic/
Endurance Swim Interval Workouts**

Anaerobic

600 m warm-up
5 x 50 m with 15 sec rest between each
5 x 50 m with 30 sec rest
5 x 50 m freestyle swim with 45 sec rest
200 m easy swim
5 x 100 m freestyle, 45 sec rest
5 x 100 m freestyle with 90 sec rest
500 m easy swim

Aerobic

400 m warm-up
5 x 200 m freestyle with 30 sec rest
10 x 100 m freestyle, keep distance pace, 10 sec rest
200 m easy swim
5 x 200 m freestyle with 5 sec rest
10 x 100 m freestyle, keep distance pace, 5 sec rest
400 m cool down

Underwater Training

Swimming underwater requires breathholding. While this is an activity that is not endorsed by the diving manual, it may be something you will need to do as a SEAL. Given this fact, specific training will enhance your performance and extend your operational capabilities. The following rules apply to underwater swim training:

- ◆ DO NOT hyperventilate prior to your underwater swim.
- ◆ Use a buddy to observe during pool drills.

Varying Your Workout

Swimming workouts should be varied between easy days and hard days. For competitive speed, it is good to swim at least four days a week; this will help keep stroke efficiency. Swimming days provide good relief for tight muscles generated by running and weight training.

Swimming has some specialized weight training techniques. The primary issue is that swimmers have full range of motion of their arms during exertion. Muscle contraction is fairly constant over the entire arm motion requiring balanced power throughout. Weight training must complement this fact, or muscle tightness develops that actually works against the swimmer (see Chapter 6).

Pulley pulls are excellent weight training techniques for a swimmer. The classic is the lat pull-down station present in virtually all weight rooms and multi-station machines. A better arrangement is for weights and pulley setups to be individualized for each hand. Pulley pulls are “isotonic” and mimic the constant resistance of water. Weights should be kept on the low side, permitting high speed weightlifting of between 1-1.5 seconds per repetition. Hold slightly at the end of each lift to prevent banging weights and getting thrown out of the weight room.

Swimmers use high reps, never less than 10.

Many dedicated swimmers own an Exergenie, which is a truly simple piece of equipment that permits a realistic workout in freestyle or backstroke. It is a nylon line rigged up through a little cylinder that twists the line and provides resistance. This workout is possible even within the confines of a cramped 688 class (40 - 50 reps) can be done daily because the motion is so much like swimming. Thus, it is a portable weight room for swimmers.

Cross training includes canoeing, rowing, kayaking, and cross country skiing.

All of these involve repetitive arm use in a pattern that is generally complementary to a swimmer's stroke. These sports will impart strength to the shoulder and chest muscles that will help your swimming.

Developing Stroke Skills

Basic stroke mechanics will prohibit you from increasing your respiratory rate (except during backstroke). Because you can't pant, you will quickly become limited by not getting enough oxygen or not getting rid of carbon dioxide before it starts building up. This is different than in running and is the reason for the universal use of interval training in swim training programs. Runners often go out for long steady runs, but a swimmer who trains this way becomes a slow and inefficient swimmer. While operational SEAL swimming is a long, slow activity, it is best for you to acquire a broad base of swimming skills. This will increase your efficiency during SEAL operational swimming.

This section will discuss three main swimming strokes; *crawl stroke* (usually called freestyle or “free”), *breaststroke*, and *sidestroke*. These particular strokes are the most useful to you as a SEAL. Most swimmers use a variety of strokes in a workout to provide cross training and avoid overuse injuries. Skills must be developed over a long period of time in order for the swimmer to become proficient. Good stroke mechanics are not only necessary to develop speed; injury may occur in swimmers from poor technique. A proper stroke may only be developed by getting feedback from others. This factor makes a buddy system or partner coaching an essential component of your training program. Obtain periodic stroke coaching from a qualified instructor - no matter how good you are.

General Stroke Principles

Water causes a large amount of drag on the swimmer's body, thus streamlining becomes extremely important. The key to swimming fast is reducing drag as much as possible while maximizing propulsive forces. One specific technique includes rolling from side to side to clear high resistance parts of the swimmer's body for arm recovery. Swimming in salt water is faster than swimming in fresh water because of the increased buoyancy of the swimmer, reducing resistance. There are many other subtle ways to reduce water drag in swimming, and learning them is one of the benefits of getting coaching from a qualified instructor or swimming coach.

The Strokes

Freestyle

For beginning freestyle swimmers, a pullbuoy will help the swimmer concentrate on proper arm stroke and additionally, help keep the hips positioned high in the water which minimizes drag. Approximately 90% of the work with the freestyle is due to the arm stroke.

The correct arm pull incorporates several elements of sculling. In overall terms, the arm of the swimmer resembles a turning propeller. The diagrams in Figure 5-4, Figure 5-5, and Figure 5-6 outline the hand motion relative to the water, and present front, side, below the water views of the free-style arm stroke of Mark Spitz, as analyzed by swimming physiologist, James Counsilman. Notice the circular motion of the swimmer's arm.

Figure 5-4. Comparing the Free-Style Stroke to the Blades Turning on a Propeller

Figure 5-5. The Free-Style Stroke of Mark Spitz

In Figure 5-5 you can see the “catch” that a championship swimmer develops as he sculls downward at first and then sweeps his hand quickly back toward his body.

As shown in Figure 5-6, you can see how the hand is used to seek out still water from below the swimmer. The swimmer initially sculls outward, then he directs his hand inward at the same time he is “catching” back upward toward his body. The freestyle stroke is then completed with an outward scull.

This view shows best the “S” shape of a proper pull. Keep in mind that the “S” occurs in both the horizontal and vertical planes - a very complex motion indeed! You can appreciate how necessary coaching is in developing a proper arm stroke.

Several of the drills are designed to break this down for you. One arm freestyle allows you to concentrate on the arm's motion. Catchup freestyle slows everything down so that you can coordinate body roll with arm pulls. Using hand paddles will help you feel the water and the sculling sensation is also greatly accentuated.

**Figure 5-6. Below the Swimmer
View
of Mark Spitz's Free-Style Stroke**

Using hand paddles will help you develop a strong sculling motion.

Other views (Figure 5-7) show how the arms move during the freestyle stroke. From the front, the hand roughly describes a loop. Finally, you can see again from a side view of Mark Spitz that there is an aggressive “catch” action in the arm pull as he sculls back toward his body.

Figure 5-7. Side and Front Views of Mark Spitz's Free-Style Stroke

Breaststroke

The key to breaststroke is the kick. Propulsion is provided by drawing the feet up towards your body in the direction of motion, and then sweeping both feet backward in a circular motion, pushing motionless water backward with the inside and bottom portions of the swimmer's feet. Coaching is essential to develop good technique as the kick is very subtle.

Pulling is done by a sweeping sculling motion. A good stroke drill to work on for a strong sculling motion is to use only your arms and not your legs, in other words, “pull breaststroke”. This drill develops a feel for the water that is needed for all three strokes.

Sidestroke

Sidestroke is extremely important for you to master. SEALs are required to swim in open water under challenging conditions. Arm pulling and kicking should be coordinated to maximize thrust and conserve energy over a long swim. It is necessary to learn sidestroke using either side in order to be able to face away from heavy ocean chop and swells. You can't afford to have a favorite side.

Sidestroke is a "stealth" stroke, unlike freestyle. SEALs can stay in contact with each other over a long swim distance. The sculling motions that have been diagrammed in this chapter for freestyle, also apply to sidestroke. Use a sweeping action with your hand and visualize that your upper hand is like a helicopter blade grabbing still water out in front of you while your bottom hand grabs water ahead and below you.

The power of fins can be used with your flutterkick, not broaching on the surface of the water. Sidestroke is efficient, conserving your energy over a long swim. With fins, the majority of thrust comes from the legs and arm stroke is less important.

Swimming Drills

Fin Drills

Kicking with fins is fantastic training. Be careful of using a kickboard too much while training with fins; this may cause back pain. Sidestroke is good but you will need lane lines and flags to prevent careening off course and acquiring a nice scalp laceration. The mainstay of kicking strokes is still prone flutterkick.

Fin kicking drills are essential to building leg strength and specific training for SEAL combat swimmer duties. These drills are effective when imbedded within a pool workout where there are swimming sets that accentuate arm and chest muscle training. This is because the swimmer's legs will be warmed up but relatively fresh and ready for a strenuous workout with fins. Use high numbers of repeats in sets, 10-12, with relatively short rest intervals of 10-15 seconds. A total set length of around 10 minutes is optimal; any longer and the set begins to degrade into a long, slow distance set which is best done in open water.

- ◆ **Fin Sprints:** Sprinting 25 meters with fins will allow you to feel flaws in your arm strokes. This drill will consume an extraordinary amount of oxygen and provide a good anaerobic and strength workout for your legs. It also feels great to go fast.
- ◆ **Fin Fartlek:** Do this set without a kickboard. Kick one length with an easy flutter kick, then flutterkick the next length on your right side with both hands out of the water - effort level high - then back to face down for a length of easy flutter kick, then back at it over a hard length, this time on your left side, again hands out of the water. Repeat several times. This drill is particularly effective in a long pool (45m).
- ◆ **Fin Repeats:** Do with a kickboard. Kick flutterkick hard for 50m, rest 10 seconds, repeat for 10 repetitions.

Other Specific Freestyle Drills

- ◆ **One Arm Freestyle:** May be done with or without a pullbuoy. Emphasizes body rolling without corkscrewing. This drill will allow the swimmer to concentrate on proper pulling technique.
- ◆ **Catch-Up Freestyle:** Hold arm out in front while pulling with the other arm. Recover the pulling arm and then touch hands out in front before initiating the pull with the other arm. This drill will help timing of pull.
- ◆ **Fist Freestyle:** Swim with fists. This will make the swimmer concentrate on forearm sculling. Do this drill without the pullbuoy.
- ◆ **Finger Drag Freestyle:** Recover arm with fingers skimming the water. This provides the swimmer with feedback regarding arm and hand position during arm recovery.

Common Problems

Swimmers often develop hypersensitivities and allergies with pool swimming. The source of the problem is the inhalation of chlorinated organic material (guess where this comes from in a public pool). These hypersensitivity reactions may include lung conditions that are quite disabling. Prevention is the key. Ways to minimize your chances of such problems include:

- ◆ Wearing goggles.
- ◆ Using a nose clip.
- ◆ Avoiding any situation where you might breathe a mist or spray that is generated from pool water.

Chapter 6

Strength Training

Muscular strength and endurance training enhance agility, speed, strength, and endurance, all of which are essential to the SEAL operator. This chapter will help to establish an understanding of the principles of muscle strength and endurance training and their application in the use of weight equipment. The focus of strength training should be its functional use for specific missions. Pure strength alone will not improve mission performance, but conversion of strength to muscle endurance should. The main objective of your strength training program should be to increase your applied strength - an increase in applied strength will enhance your performance on physical tasks required during missions. As such, this chapter introduces concepts and practical information for achieving optimal muscle strength and endurance for job performance and prevention of injuries.

Weight Training Gear and Equipment

Weight training requires minimal personal gear. Other than the weights themselves, equipment such as a pair of supportive shoes, fitted lifting gloves, and standard PT attire is all that is needed. A weight lifting belt should be used for back protection.

Technology has allowed the development of exercise equipment that efficiently adapts to the changing needs of a body in motion. Consider the choice of free weights, machines, or a combination of both for development of strength and balance when starting a weight training regimen. Table 6-1 presents a comparison of free weights and machines.

Table 6-1. Free Weight and Exercise Machine Comparison

Issue	Free Weights	Exercise Machines
User Friendliness	Usually available; Require minimal space; Require spotters for some evolutions	Must have access to sophisticated equipment; Doesn't require spotters
Skill	Require more skill than machines	Require less skill than free weights; Easy to use
Type of Movement	Dynamic	Limited range of motion
Variety in Workout	Allow for a variety of exercises; Useful for correcting strength imbalances between muscles on both sides of the body	Provide variable resistance; Availability of equipment may limit variety
Application	Primary muscles plus peripheral muscles	Tend to isolate muscles

Strength Training Guidelines and Terms

Performing operational tasks requires all muscles of the upper and lower body to be developed in a balanced way. *Circuit weight training or Split-routine workouts* are the most common ways to maintain a musculoskeletal balance. Circuit weight training consists of a progression from one station to the next such that over the course of the training period, both the upper and lower body are exercised. For split-routine training, different body areas are exercised on alternate days. For example, on Monday and Thursday, the upper body would be exercised whereas on Tuesday and Friday the lower body would be exercised. By having a well designed strength program, you can expect to maintain a high level of fitness while reducing your risk of injury and fatigue.

Repetition Maximum or RM

One term routinely used in strength training is that of repetition maximum. A **repetition maximum or RM is the maximum amount of weight you can lift for a given number of repetitions.** For example, your 1RM would be the amount of weight you could lift for only 1 repetition. Your 5RM would be the amount of weight you could lift for 5 repetitions. For example: if a SEAL can do 5 repetitions of an exercise with 50 lbs., he has a 5RM of 50 lbs.

Your 1RM would be the amount of weight you can lift for only 1 repetition

FITT: Frequency, Intensity, Time, Type

In order for the SEAL operator to perform mission-related tasks, strength training is a key aspect that must not be overlooked. Understanding the concepts of **Frequency, Intensity, Time, and Type (FITT principle)** will help you understand and maximize your training.

The **FREQUENCY** of training should be determined by the amount of time one has to spend on strength training. As SEAL operators, your weight training time is limited due to busy schedules, so keep this in mind when you start a program. For example, total body circuit training only needs to be performed twice a week, along with other training modes for optimal results. If two days of training cannot be achieved, one session will be better than none. Split-routine training should be performed a minimum of two sessions per muscle group weekly to ensure total muscular balance, and thus consumes a greater amount of time than circuit training.

Circuit weight training optimizes the time available for SEAL operators.

Training **INTENSITY** is considered to be the most critical aspect of strength and conditioning. Intensity of weight training can be referred to as load, which is the amount of weight per repetition. It is defined as the percentage of the RM that is being used to perform an exercise. Various intensities are recommended for optimal results. The program phase focusing on muscular endurance would involve training at 30% to 50% of your 1RM with 20 to 60 repetitions per set. In contrast, the phase focusing on strength development would require training at 65% to 90% of your 1RM, with 1 to 12 repetitions per set, depending on the week of training (Table 6-1). SEAL training should focus on both strength and muscular endurance, and cycle between 30 and 90% of maximal strength. This approach will yield maximum results and increase your performance as a SEAL operator.

The **TIME** you spend on weight training might vary depending on the program chosen. Generally, 30-60 minutes is sufficient, whether a circuit or split routine is implemented.

The **TYPE** of exercise will vary throughout your strength program and can include free weights or machines. For platoon evolutions, circuit training is more adaptable, while split routines may be used for individual strength programs. Figure 6-1 provides an example of the **FITT** principle.

Strength training, along with various other mission-related practices (such as obstacle courses, swims, runs, jumps, and climbs) will develop an overall well-conditioned SEAL operator.

Figure 6-1. Applying the FITT Principle to Total Body Circuit Weight Training

Total Body Circuit

- F:** 2 times weekly
- I:** 30% to 90% of 1RM
- T:** 30 to 60 minutes
- T:** Circuit weights

Muscle Balance and Exercise Selection List

It is extremely important to consider muscle balance when designing your workouts. Building strength in the triceps should be balanced by strengthening the biceps, and strengthening the quadriceps should be balanced by strengthening the hamstrings. **Without proper balancing of opposing muscle groups, you become vulnerable to injury.**

The main goal of a weight training regimen is to produce a gain in overall strength for operational tasks.

Many exercises can be incorporated into your strength training program. **Table 6-2 presents a list of exercises by specific body parts, all of which are demonstrated in Appendix A.** This translates into a complete body workout from the calves to the neck.

Table 6-2. Exercise Selection List by Body Part

Body Part		Exercises
Legs:	Squats	Leg Extensions
	Leg Press	Leg Curls
	3/4 Squat	Leg Press
	Standing Calf Raises	
Back:	Curl Grip Lat Pulldown	One Arm Dumbbell Row
	Reverse Barbell Row	Hyperextensions
Chest:	Bench Press	Incline Dumbbell Press
Shoulders:	Behind-the-Neck Press	Upright Row
Arms:	Triceps Pressdowns	Curls

Determining Repetition Maximums

The purpose of knowing your RM is to allow you to adjust the exercise intensity. As a safety measure, it is best to start out by determining your 5RM. To do this, you should have not had any strenuous activity on the day of the test, and you should be properly warmed up. A spotter should always be available when conducting this test. Free weights are the recommended form of weight for this test.

- ◆ Select a weight you know is light enough for 10 repetitions.
- ◆ Perform 10 - 15 repetitions with that weight.
- ◆ Rest for two minutes.
- ◆ Increase weight 2% - 10%, depending on difficulty of previous set.
- ◆ Perform 6 - 8 repetitions.
- ◆ Rest for two minutes.
- ◆ Increase weight 2% - 10%, depending on difficulty of previous set.
- ◆ Rest for three minutes.
- ◆ Perform 5 repetitions - this should be close to your 5RM.

Perform sets with increasing weights and decreasing repetitions until a weight that can be comfortably handled for 5 reps is reached.

Table 6-3 provides an example of how you might determine your 5RM for the bench press, starting with a weight of 110 lbs. Typically, your 5RM is 87% of your 1RM, and your 10RM is 75% of your 1RM. Thus, if your 5RM is 160, your 1RM would be approximately 184 lbs, and your 10 RM would be about 138 lbs. After determining your 5RM, it will be easy to establish your 1RM and loads for workouts (See Figure 6-2). See Table 6-4 for intensity as a percent of maximum strength, repetitions, energy systems, and rest intervals. Remember, the three energy systems are:

- ◆ ATP-PC System for speed work activities, such as sprinting.
- ◆ Lactic Acid and ATP-PC System for all-out exercise that continues beyond 30 seconds, but lasts less than 3 minutes.

- ◆ Oxygen system for aerobic energy to support long-term steady state exercise, such as long distance running or swimming.

Multiply your 5RM times 1.15 to establish your 1RM.

Figure 6-2. Determining Your 1RM from 5RM

$$\begin{aligned}5\text{RM} &= 75 \\1\text{RM} &= 75 \times 1.15 = 86 \\5\text{RM} &= 136 \\1\text{RM} &= 136 \times 1.15 = 156\end{aligned}$$

Table 6-3. How to Determine Your 5RM for a Bench Press

Set	Repetitions	Weight	Rest Intervals Between
10 Minute Warm-Up			
1	12 - 15	110 lbs	2 minutes
2	10 - 12	120 lbs	2 minutes
3	6 - 8	135 lbs	3 minutes
4	5	160 lbs	Completed

Table 6-4. Intensity Levels Relative to a 1RM*

% of 1RM	Number of Repetitions	Rest Intervals Between Sets (minutes)	Energy System
≥ 95	1	3 - 5	ATP/CP
80 - 95	2 - 5	3 - 5	ATP/CP
65 - 80	6 - 10	2 - 4	ATP/CP/LA
50 - 70	8 - 15	2 - 4	ATP/CP/LA
30 - 50	15 - 60	1 - 2	LA/Aerobic

Periodization

Periodization of training is a technique that involves altering training variables (such as the number of repetitions per set, the exercises performed, training intensity, and the amount of rest between sets) to achieve well-defined gains in muscular strength, endurance, and overall performance. For example, if you were working towards a particular mission or athletic competition, you would want to peak at that moment and not earlier. Your training schedule would be adapted to achieve that goal.

There are several phases to periodization and weight training in general. The first phase is one of activation, or getting the body ready for a new activity. It would typically last four weeks. Most of you are already weight training and thus have completed the true activation phase, but it is okay to start anew. The second phase is for strength development, and it would last about 4 to 7 weeks, depending on how long you have been weight training. The next phase is the muscular endurance phase, and lasts 8 to 12 weeks, depending on your schedule. Table 6-5 presents a one year plan for training, with three seven week periods of strength development followed by 12 weeks of conversion to muscular endurance. Note that this schedule can be modified, and is presented here to emphasize the concept of periodization.

The goal of the muscular endurance phase is to take strength gains and convert them

into applied strength for operations.

Table 6-5. An Annual Plan for Activation, Strength Development and Muscular Endurance*

Sept	Oct	Nov	Dec	Jan	Feb	Mar	April	May	June	July	August
Develop Strength		Muscle Endurance			Develop Strength		Muscle Endurance			Cross-Training/ Active Rest	Develop Strength

*Adapted with permission from *Strength Training for Sports*; Applied FuturisticsSM, Inc.

Training intensities should be varied weekly, depending on whether you are in the strength or muscular endurance phase. Table 6-6 and Table 6-7 present the percent of maximum (% 1RM) and number of sets for the strength and muscular endurance phases, respectively. These templates can serve as guidelines for creating your own periodized program. Remember, this program should be followed two times per week.

Table 6-6. Strength Development Phase: 2-Day Circuit Weight Training Routine

Week	Set 1	Set 2	Set 3	Set 4	Set 5
Perform a 5RM test to start Week 1					
1	50% X 12	70% X 8	70% X 8	80% X 6	80% X 6
2	50% X 12	70% X 8	80% X 4-6	80% X 4-6	85% X 3-5
3	50% X 12	75% X 8	85% X 3-5	85% X 3-5	90% X 3-5
4	45% X 15	75% X 6-8	75% X 6-8	80% X 4-6	80% X 4-6
5	55% X 12	75% X 8	85% X 3-5	85% X 3-5	85% X 3-5
6	55% X 10	75% X 8	85% X 3-5	90% X 1-3	90% X 1-3
7	55% X 12	75% X 6-8	75% X 6-8	80% X 4-6	80% X 4-6

Table 6-7. Muscle Endurance Phase: A 2-Day Circuit Weight Training Routine

Week	Set 1	Set 2
Perform a 5RM test at Week 1		
Start at 30%: Reps are more important than%		
1	30 - 50% X 20	30 - 50% X 20
2	30 - 50% X 30	30 - 50% X 30
3	30 - 50% X 40	30 - 50% X 40
4	30 - 50% X 35	30 - 50% X 35
5	30 - 50% X 45	30 - 50% X 45
6	30 - 50% X 50	30 - 50% X 50
7	30 - 50% X 40	30 - 50% X 40
8	30 - 50% X 55	30 - 50% X 55
9	30 - 50% X 60	30 - 50% X 60
10	30 - 50% X 50	30 - 50% X 50
11	30 - 50% X 40	30 - 50% X 40
12	30 - 50% X 30	30 - 50% X 30

Although it may seem a bit foreign to you to see up to 60 reps per set in Table 6-7, this is the best way to convert your strength gains to applied strength, or functional strength. You will be amazed at your muscular endurance and ability to perform mission-related tasks and other strenuous physical tasks, if you truly stick with a program such as this

Weight Lifting Techniques

Correct lifting techniques are critical for achieving maximum benefits and preventing injury. Lifting form, speed, and breathing techniques are all important for weight training. The lift should be performed as a controlled movement with proper form. Do not compromise your form as it will not help but rather increase your chance of injury. The appropriate speed of lifting needs to be applied to all exercise movements. When performing exercises, such as the bench press, squat, biceps curl, lat pull-down, etc., the weight should be moved at a rate of 1-2 seconds in each direction. This will ensure your safety and optimize strength training.

Controlling the rate of movement affects the muscle you intend to strengthen.

Always make use of a spotter if you are using free weights. Refer to Appendix A for form illustrations and instructions, so you can change your technique if you are not following the proper directions.

Exhale when moving a weight against gravity.

Proper breathing techniques must be used during weight training. Exhale during positive weight movement (moving the weight against gravity). This helps prevent the valsalva maneuver (an increase in internal pressure caused by holding your breath during lifting exercises) which can result in damage to the cardiovascular system. Never hold your breath while performing any exercise task.

Types of Workouts

A *Circuit Routine Training* for the first week of the strength development phase and muscular endurance phase is presented in Table 6-8 and Table 6-9, respectively. Workouts for the other weeks can be obtained by reviewing Table 6-6 and Table 6-7. Remember, periodization is the key to improving overall muscle strength and endurance.

Table 6-8. Week 1: Circuit Training Strength Development Phase

Exercises	Sets (% of 1RM and Reps)				
	1 (%/Reps)	2 (%/Reps)	3 (%/Reps)	4 (%/Reps)	5 (%/Reps)
Squats or Leg Press	50/12	70/8	70/8	80/6	80/6
Curl Grip Pulldowns	50/12	70/8	70/8	80/6	80/6
Leg Curls	50/12	70/8	70/8	80/6	80/6
Bench Press	50/12	70/8	70/8	80/6	80/6
Standing Calf Raises	50/12	70/8	70/8	80/6	80/6
Behind-the-Neck Press or Upright Row	50/12	70/8	70/8	80/6	80/6
Tricep Pressdown	50/12	70/8	70/8	80/6	80/6
BB Curls	50/12	70/8	70/8	80/6	80/6

DB = Dumbbell; BB = Barbell; See Appendix A for pictorial representation.

Table 6-9. Week 1: Circuit Training Muscle Endurance Phase

Exercises	Set 1 (%RM/Reps)	Set 2 (%RM/Reps)
Squats or Leg Press	30-50/20	30-50/20
Curl Grip Pulldowns	30-50/20	30-50/20
Leg Curls	30-50/20	30-50/20
Bench Press	30-50/20	30-50/20
Standing Calf Raises	30-50/20	30-50/20

Table 6-9. Week 1: Circuit Training Muscle Endurance Phase

Exercises	Set 1 (%RM/Reps)	Set 2 (%RM/Reps)
Behind-the-Neck Press or Upright Row	30-50/20	30-50/20
Tricep Pressdown	30-50/20	30-50/20
BB Curls	30-50/20	30-50/20

DB = Dumbbell; BB = Barbell; See Appendix A for pictorial representation.

Warming Up

It is imperative to warm-up prior to a strength training workout. An active and dynamic warm-up will elevate the body temperature so that the muscles respond better to the training. An increase in circulation to the joints and tissues allow more elasticity and may decrease the risk of injury. The warm-up should last long enough to break a sweat then stretching should be initiated. Thus, the major component of a warm-up session for weight training is a cardiovascular workout, or a general warm-up designed to increase your circulation and direct blood flow to the muscles for the upcoming workout. This should be low intensity exercise for 10 to 20 minutes.

- ◆ Biking
- ◆ Stairclimber
- ◆ Treadmill/Jogging
- ◆ Jumping Rope
- ◆ Rowing Ergometer
- ◆ Jumping Jacks/Calisthenics
- ◆ One or Two Exercises with Light Weights

Cooling Down and Stretching

Upon the completion of a training routine, cooling down and stretching should not be overlooked. The cool-down should be gradual to normalize body temperature, prevent pooling of blood in the muscles and return metabolic rates to pre-exercise levels. It also speeds the removal of waste products which tend to increase muscle soreness and prolong recovery. Stretching after weight training maintains joint and muscle flexibility while minimizing muscle spasms and weight training injuries. In brief, the components of a cool down include:

- ◆ Low intensity cycling or walking.
- ◆ Complete body stretching.
- ◆ Relaxation.

Common Problems

You need to listen to your body and be able to recognize the signs of problematic conditions associated with weight training.

- ◆ **Injuries** - Lack of warm-up and improper lifting techniques (form) can cause muscle damage.
- ◆ **Overuse Syndrome** - occurs when you engage in frequent repetitive exercises to a specific area or use an improper technique during an exercise. The knee, elbow, and shoulder are most susceptible to these injuries.
- ◆ **Delayed Onset Muscle Soreness (DOMS)** - potentially severe pain experienced 24 to 48 hours after the activity.

In order to allow the body to heal, the improper routine and/or techniques must be altered. Proper technique, progression, variation, rest and recovery will minimize training related injuries. More information can be found in the training related injuries chapter.

Conclusions

Strength training with weights is an important component to the complete PT program of the SEAL operator. Training with weights 2-3 times per week can help optimize preparations for mission-related tasks. It is important to understand that one should focus on the SEAL mission when developing a weight training regimen. A proper weight training routine will help prevent injuries and accelerate recovery from an injury to the musculoskeletal system. Following the principles and examples in this chapter will help you develop a well balanced lifting routine. Optimal conditioning can be obtained without injury to the body if weight training is included in your overall “PT” program.

Acknowledgment

The editors thank Mr. Fred Koch for sharing his expertise and experience in strength training. His comments and suggestions were invaluable to the development of this chapter.

Chapter 7

Flexibility

Most trainers, exercise physiologists, and health care professionals agree that flexibility training, although often overlooked, is an important component of a physical fitness program. Stretching becomes even more important as athletes and/or SEALs achieve advanced levels of muscle strength and endurance. If optimum performance is the goal, then adherence to a consistent flexibility program is required.

Flexibility Benefits

Proper use of stretching increases flexibility and provides the following benefits:

- ◆ Improved performance.
- ◆ Reduced potential for injury (i.e., muscle strain or sprain).
- ◆ Reduced muscle soreness.
- ◆ Decreased risk and severity of low-back pain.
- ◆ Increased agility.
- ◆ Increased blood flow to the joints.

Proper physical conditioning is necessary for successful mission performance. Flexibility is an integral part of a conditioning program and enhances performance by extending the range of motion in which one can optimally perform. SEALs are at high risk for musculoskeletal injuries. Joint stability and consequent protection against injury are best achieved through a

balanced physical conditioning program designed to improve both muscle strength and flexibility. Strength and flexibility training should be considered interdependent since both are involved in the degree and quality of movement across a joint.

Muscles that are strengthened should be stretched, and vice versa. An intense strength workout can cause microtrauma to the muscles, and the process of recovery can shorten the muscles and connective tissue. Stretching prevents this shortening which could contribute to muscle strains or other overuse injuries (e.g., tendonitis, fasciitis).

Flexibility training, without concurrent strength training, weakens the muscles and connective tissue and places the joints and muscles at risk for sprains, partial and complete dislocations, and muscle strains. Strengthening the muscles surrounding a stretched joint helps stabilize the joint and improve muscular function, thus decreasing the likelihood of injury.

Overstretching may lead to injury; however, as long as a flexibility program is well balanced with strength training, this possibility is negligible.

Definition

Flexibility is the ability of a limb to move freely about a joint through a full range of motion.

In the case of Special Warfare Operators, flexibility refers to the optimum range of motion surrounding a particular joint that is necessary for peak performance. Range of motion is specific to each joint and dependent upon:

- ◆ Joint surfaces and capsule and the degree of movement required for the joint to function.
- ◆ Muscles, tendons, ligaments and connective tissue associated with limb movement around a joint (for definitions see Chapter 1).
- ◆ Strength of the musculature surrounding the joint.

**There are two types of flexibility:
dynamic and static.**

Dynamic or active flexibility refers to the speed attained within a range of motion at the joint during physical performance. This type of flexibility involves the intrinsic musculature surrounding the joint and its ability to overcome resistance to motion. An example would be the flexibility required to throw a baseball, punch a boxing opponent, or

perform a martial arts kick. Static or passive flexibility refers to the maximal range of motion of a joint during passive movement induced by an external source (e.g., a partner, equipment, gravity). The range of static flexibility is always greater than that of dynamic flexibility.

The Stretch Reflex and the Lengthening Reaction

The stretch reflex and the lengthening reaction are joint-protective mechanisms in which sensory organs, located in the muscles and tendons surrounding a joint, are activated when muscles are stretched. As seen in Figure 7-1, the two sensory organs involved in monitoring muscle tightness are the muscle spindle cells and golgi tendon organs (GTOs).

Figure 7-1. Graphical Representations of Muscle Spindles and Golgi Tendon Organs

The stretch reflex involves muscle spindles which lie parallel to the muscle fiber. These spindles are very sensitive to changes in muscle length. When the muscle stretches, muscle spindles send signals to the spinal cord, which in turn, sends signals to the muscle telling it to contract in order to protect the muscle from potential tissue damage. The classic example of the stretch reflex occurs when a physician taps a patient just below the kneecap.

The quadriceps muscle is quickly stretched, and the muscle spindles react by contracting the quadriceps muscle causing the knee-jerk response. The greater or more rapid the stretch, the greater the response of the muscle spindles and the resultant muscle contraction. Signals are high in frequency at the beginning of a stretch, but then slow down as they adapt to the new length.

The lengthening reaction engages GTOs, which are located in the muscle-tendon junctions, and activates them when the tension in a tendon is increased as a result of either muscular contraction, stretching the muscle beyond its resting length, or a combination of the two. When muscular tension increases, the GTOs respond by sending inhibitory signals to the muscle; this causes the muscles to relax, and protects the muscles and tendons from tearing due to tension overload. Knowledge of the stretch reflex and the lengthening reaction is useful for effective stretching.

The most effective stretches are performed slowly, and held for 15 - 30 seconds.

Performing the stretch slowly avoids excessive activation of the muscle spindles and resultant muscular contraction. Holding the stretch allows time for the muscle spindles to adapt to the new muscle length, and eventually, to achieve greater lengths. The length and duration of the stretch should also be sufficient to activate the GTOs so that they override the muscle spindles and induce muscular relaxation.

Flexibility Training Methods

There are several training methods used to develop flexibility; however, most fall under the following general categories:

- ◆ Dynamic
- ◆ Static
- ◆ Ballistic
- ◆ Proprioceptive neuromuscular facilitation (PNF)

Dynamic Stretching

Dynamic stretching (sometimes referred to as active stretching) consists of controlled movements which increase in range and/or speed so that you gradually reach your full range and speed of movement (e.g., slow, controlled leg swings or kicks, controlled arm swings, back bends). This type of stretching often mimics the activity that is to be performed and prepares the muscles for that activity.

There is some controversy surrounding the effectiveness of dynamic stretching and its role in the development of flexibility. Some experts believe that the short, intermittent movements involved in this type of stretching activate the stretch reflex and cause the stretched muscle to contract. Others maintain that dynamic stretching is beneficial for quick, explosive activities like gymnastics or martial arts. However, in general, dynamic stretching should not be used to develop static flexibility or long-standing changes in range of motion. If used at all, dynamic stretching functions best before exercise to enhance performance. This type of stretch is often performed after a warm up and prior to an exercise session in anticipation of a particular activity. Dynamic stretches should mimic the activity that is to be performed.

Static Stretching

Static stretching (sometimes referred to as passive stretching) develops static flexibility and uses slow, controlled movements through a full range of motion. This type of stretch is performed by holding a position using a part of the body, the assistance of a partner, or some other apparatus such as a pole or the floor (e.g., lifting one leg up and holding it with the hand, the splits). Slow, static stretching helps relieve muscle spasms due to exercise, and is used for cooling down after a workout to reduce muscle fatigue and soreness.

Ballistic Stretching

Ballistic stretching uses the momentum of the body or a limb to force a stretch past the normal range of motion and then return to the starting position. Ballistic stretching incorporates bouncing or jerky movements and should not be confused with dynamic stretching. An example of a ballistic stretch would be bouncing down to touch toes or using the momentum of the torso to twist the body. Uncontrolled arms swings in which the arms are thrown backward and then bounce back to the starting position are also an example. This type of stretching does not contribute to flexibility. Instead, the repeated activation of the stretch reflex causes muscles to contract which can lead to injury. **This type of stretching is not recommended.**

PNF Stretching

Proprioceptive neuromuscular facilitation (PNF) stretching is considered an advanced stretching technique. It is used extensively by physical therapists or when high degrees of both passive and dynamic flexibility are required for performance (e.g., martial arts, ballet, gymnastics, kick-boxing). There are several PNF techniques, but generally, PNF consists of a passive stretch, followed by an isometric contraction, which is then followed by another stretch (static or dynamic). By combining passive stretching with isometric contractions (a contraction in which there is no change in muscle length or joint movement) with a partner or object for resistance, PNF uses the stretch reflex and lengthening reaction to achieve a greater range of motion. As described in the section

above, when a muscle is slowly stretched and held, the resulting tension triggers the lengthening reaction which prevents the stretched muscle fibers from contracting. When this stretched muscle is then isometrically contracted, the following happens:

- ◆ During an isometric contraction, some fibers will contract, but others will stretch even further. When the contraction is stopped, the contracted fibers return to their starting position, while the stretched fibers retain their stretched position (due to muscle spindle accommodation) and are able to lengthen even further.
- ◆ The increased tension within the muscles generated by an isometric contraction activates the GTO which triggers the lengthening reaction, and inhibits further contraction. When the isometric contraction is stopped, the muscle is still inhibited from further contraction and able to lengthen further.

The final stretch, which follows isometric contraction, takes advantage of the muscle's ability to elongate further, and allows the muscle, tendon, and sense organs to adapt to greater lengths.

It is best to have a partner help when using PNF techniques.

A common PNF technique is referred to as the **“contract-relax method”**. Instructions for and a pictorial representation of this method are provided in Figure 7-2. This technique uses passive stretch and isometric contractions, followed by muscle relaxation and passive stretching to the new range of motion. For example, if you are stretching your hamstrings, you first passively take the stretch to the point of tightness and hold. Then you isometrically contract the hamstrings by using this muscle to apply force against an object or partner (See Figure 7-2). Following the contraction, the muscle is allowed to relax and the muscle is then passively stretched and held. Current recommendations suggest performing this technique with one to five repetitions, but like weight training, it needs to be done no more than three to five times a week.

Figure 7-2. Contract-Relax PNF Technique

1. Passive stretch for 15 sec
2. Isometric contraction for 7 - 15 sec
3. Passive stretch to new end ROM for 15 sec

Repeat 1 - 5 times

It is interesting to note that many stretches (including some of those illustrated in this chapter) can be performed statically, dynamically, or using PNF, depending on the goals of a stretching program.

Warming-Up and Stretching

Stretching is not the same as a warm-up.

Many individuals stretch in a misguided attempt to warm-up; however, stretching and warm-up should be considered distinctly different activities. A warm-up prepares the body for the activity that is to follow. The two types of warm-up are general and activity-specific. Physiologic changes that occur during warm-up include increases in muscle temperature, blood flow, oxygen delivery to the muscles, and skeletal muscle metabolism. Warm-up benefits include injury prevention and an improvement in performance.

A warm-up should always precede any

physical activity whether it be stretching, exercise, sports, or mission-related training.

Cold muscles don't stretch, and there is a high chance of injury when stretching is performed without first warming up. Stretching (especially dynamic stretching) may be part of (or follow) a warm-up, but should not exclusively comprise the warm-up.

Stretch only after an adequate warm-up has been performed.

General Warm-Up

General (or unrelated) warm-up involves movements (e.g., running in place, jumping jacks, and other calisthenics) that are different from, or unrelated to, the specific activity that is to follow. This type of warm-up should be performed prior to high-intensity activities (e.g., O-Course, power-lifting, “burn-out PT,” gymnastics, etc.) when immediate participation in the actual activity is likely to result in joint or muscle injuries.

Activity-Specific Warm-Up

Activity-specific (or related) warm-up occurs with a low-intensity version of the activity that is to follow. Examples of activity-specific warm-up include a slow jog prior to a long run; slow cycling in preparation for a cycling event; or slow karate moves prior to practice. A related warm-up starts out slowly and progresses to more intense activity. Depending on the intensity of exercise to be performed, a warm-up of anywhere between 10 - 30 minutes may be required--the greater the intensity of the workout, the longer the warm-up.

All warm-ups should be of sufficient intensity to elevate body temperature; sweating is a good indication that you are ready to move on to the next phase of your workout.

Both general and activity-specific warm-ups may incorporate some type of stretching, especially if the activity to be performed is one of high intensity and imposes a good chance of acute injury. After a short period of warming-up, some pre-exercise stretching should be done. Figure 7-3 provides several examples of warming-up for various activities. If time is limited, the pre-exercise stretch can be eliminated but a static stretching program should follow every exercise session.

Figure 7-3. Specific Warming-Up Activities

O'Course

10 - 20 min of Calisthenics or Slow Jogging

Dynamic Stretching of Major Muscles

A Long Run

10 - 15 min of Slow Jogging

PT

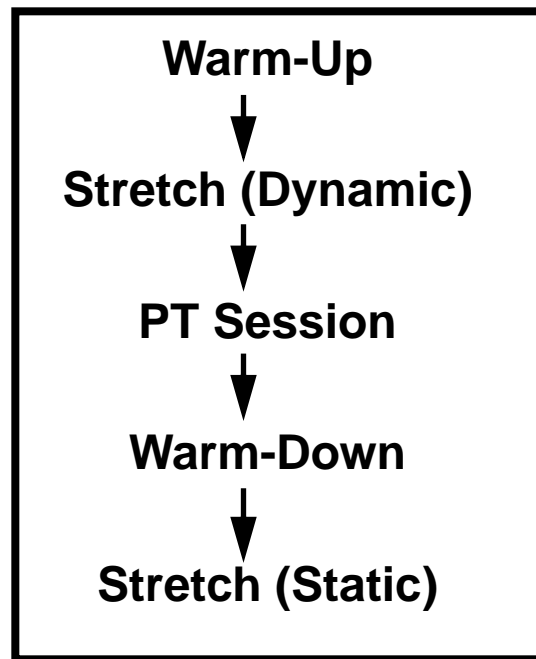

Jumping Jacks, Slow Jog or Other In-Place Activity for 10 - 20 min

Dynamic Stretching of Muscles to be Used in PT

Exercise should not be ended abruptly, but gradually slowed, to avoid pooling of blood in the skeletal muscles, and to facilitate the removal of metabolic end products. Exercise should be followed by a cool-down and stretching session.

Since most of the benefits from stretching occur post-exercise, a 10-15 minute stretching program should follow every exercise session, and should be incorporated as part ~~of the warm-down while the muscles are still warm. Stretches should be slow and static,~~ held for 15-30 seconds, and taken to the point of tightness, not pain. Static stretching provides a good warm-down after a workout, reduces post-workout muscle fatigue and soreness, and is useful for relieving muscle spasms that occur as a result of exercise. Once muscles have been stretched, standing in cool/cold water, or running cool water over the legs or muscles used during the exercise, can also reduce soreness, and seems to speed recovery between exercise bouts. Figure 7-4 represents the ideal recommended exercise sequence.

Figure 7-4. Recommended Exercise Sequence

Recommended Stretches

Dynamic Stretching

Dynamic stretches of the muscle groups to be exercised during PT should be performed following a warm-up. Dynamic stretches should not be jerky movements. In fact, any slow, controlled movement that simulates the activity to be performed, executed for approximately 2 seconds, is sufficient. Some suggested dynamic exercises are provided in Table 7-1.

Table 7-1. Dynamic Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Neck Rolls	No count exercise: From a standing position, slowly roll the head to the side, toward the back, to other side, etc.	Neck muscles
Hi Jack, Hi Jill	4-count exercise: Begin from a standing position, with one arm elevated above the head, and other arm down and slightly away from body. On count 1 both arms are pulled backward, stretching chest muscles, and released. Count 2 repeats first movement. On count 3, arms exchange positions and again pull toward back and release. Repeat this movement on count 4.	Chest and anterior shoulder muscles
Up Back and Over	3-count exercise: Begin from standing position, arms at sides. On count 1, bring both arms forward and upward. On count 2, bring both arms down and back. On count 3, bring both arms forward, up, back, and around to complete a full circle.	Shoulders, chest, and back

Table 7-1. Dynamic Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Press-Press-Fling	<p>3-count exercise: Begin from a standing position with arms bent, fists midline at chest level, and elbows out to the side. On count 1, pull elbows backwards towards the midline of the back, stretching the chest muscles, and release. Repeat the same movement on count 2. On count 3, extend the arms out and backwards, stretching the chest muscles.</p> 	Chest and anterior shoulder
Standing Toe Pointers	<p>No count exercise: Start from a standing position with body weight over the heels. Flex and extend the feet and toes. Stretch should be felt in both the calf muscles (gastrocnemius) and muscles in front of the shins (anterior tibialis). As an alternative, walk on the heels with toes pointed upward.</p> 	Gastrocnemius and anterior tibialis muscle. (A good pre-running stretch.)
Four-Way Leg Swings	<p>No count exercise: Standing upright, slowly swing 1 leg to front and to back and to side, and across front or back of body. Swing should be a slow, controlled movement. Pointing the toes up or forward will stretch different muscles in leg.</p> 	Hip and lower leg muscles

Table 7-1. Dynamic Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Four-Way Lunges	<p>No-count exercise: Begin from a standing position. Extend 1 leg forward into a lunge so that body weight is distributed on both legs. When lunging forward, the knee should not extend beyond the toe of that leg. Use the forward leg to push off and return to starting position. Repeat this movement, using the same leg, to the side. Then, perform exercise with the opposite leg.</p>	Leg muscles
		
		
Trunk Rotations	<p>4-count exercise: begin in a standing position with legs shoulder-width apart, knees slightly bent. On count 1, bend forward at the waist flexing torso. On count 2, bend torso laterally. On count 3, extend torso backward, and on count 4, bend torso laterally to remaining side. When bending backward, keep legs slightly bent to avoid hyperextending back.</p>	Abdominal muscles, including obliques and hip flexors
		
	 	

Table 7-1. Dynamic Stretch Exercises to be Used in Physical Training

Name	Description		Muscle Group(s)
Trunk Twisters	No count exercise: Starting from a seated position with hands behind the head, twist the upper torso to one side, and then to the other.		Abdominal muscles, including obliques
Trunk Bending Fore/Aft	No count exercise: Standing straight, knees slightly bent, bend the trunk forward and then back.		Hip flexors

Static Stretching

Most of the benefits derived from flexibility training are obtained with a consistent, post-exercise, static stretching program. The stretching that is performed following exercise on one day helps to prepare the muscles for the next day's exercise session.

The following exercises (Table 7-2) can be incorporated into a post-exercise stretching program by selecting 1-3 stretches for each anatomical location listed below. Remember to balance the front of the body with the back (e.g., hip extensors with hip flexors, hamstrings with quadriceps). Select more stretches for those body areas exercised (e.g., legs after a run, shoulders after a swim). Perform 2-5 repetitions per stretch, hold for 15-30 seconds, then relax for 10-15 seconds. Note: these stretches are all no count exercises.

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Neck		
Lateral and Forward Neck Stretch	<p>In a standing position, clasp hands behind back, with left hand grasping right wrist. Bend head to left bringing left ear toward left shoulder, while slowly pulling down on right arm with left hand for added stretch (do not shrug shoulder up to ear). Stretch should be felt on right side of neck and shoulders. Perform stretch on left side by grasping left wrist with right hand. Bring right ear toward right shoulder while pulling down on left arm with right hand. Return to upright position and flex head forward and down using either hand to hold stretch. Return head to upright position.</p> 	Neck muscles
Shoulders, Chest, and Arms		
Chest Stretch	<p>Begin from a standing position with arms extended to side at shoulder level. While keeping thumbs pointed up, extend arms backward. Either have another person hold stretch or use a pole for resistance.</p> 	Anterior shoulder and chest muscles
Swimmer's Stretch	<p>Perform seated. Clasp hands together behind lower back, palms up, thumbs pointed down. While bending over from waist, slowly pull arms up and toward head.</p> 	Chest and anterior shoulder muscles

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Upper Back Stretch	While standing or seated, extend and clasp arms together in front of body turning palms outward and pressing forward until shoulders and back are rounded.	Posterior shoulders, upper back, and triceps muscles
Posterior Shoulder Stretch	Bring arm that is to be stretched across chest. Use opposite arm to pull arm being stretched toward chest until stretch is felt in posterior shoulder.	Posterior shoulder muscles
Forearm/Wrist Stretch	Begin with knees and hands on deck, wrists turned so fingertips are pointing toward knees, thumbs to outside. Keep palms flat, and lean back, stretching front part of forearm.	Forearm and wrist muscles
Triceps Stretch	Standing erect, bring arm to be stretched up and back so that elbow is pointing toward sky and hand rests between shoulder blades. Gently pull arm toward midline behind head to stretch triceps muscle. NOTE: To extend stretch down side of body, bend to opposite side of arm being stretched.	Triceps muscles

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Torso: Abdominals and Back		
Supine Back Stretch	<p>While lying on back (supine), bring both knees up and toward chest. Place hands behind knees and gently pull both legs toward chest, stretching back muscles. Excellent stretch for lower back. Can help relieve muscle spasm and reduce risk of injury (muscle strain) to back muscles. When performing stretch, one may initially feel increased tightness or pain. HOLD stretch until you can feel muscles relax and tightness subside. May hold stretch for as long as a minute.</p> 	Back extensor muscles
Overhead Trunk Side Stretch	<p>This exercise may be performed from a standing position or while lying on deck. From a standing position with arms above head, grasp wrist of arm on side that is to be stretched, and slowly bend torso to opposite side that is to be stretched. Return to starting position and repeat on other side. While lying on side, slowly lift torso off deck and hold.</p> 	Abdominal muscles
Torso Prone Stretch (Press-Ups, Lizard)	<p>Begin lying on stomach (prone) with hands flat on deck as for a push-up. Extend arms so that upper torso lifts off deck.</p> 	Abdominal muscles
Hips		
Hip Cross-Over	<p>Begin from a lying position (on back) with legs extended. Bring one knee toward chest at a 90° angle. Using opposite hand, pull leg over other leg and toward floor. Stretch should be felt in lower back and side of hip.</p> 	Iliotibial band and hip abductor muscles

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Iliopsoas Stretch	<p>This exercise is essentially a standing lunge with a pelvic tilt. Begin from a standing position. Step forward with one leg, placing one foot in front of the other. Keep both legs slightly bent. Weight should be distributed toward the front foot. Flatten the back and tuck the hips under, stretching the iliopsoas muscle on the front of the back leg. For added stretch, either lean slightly back with the upper torso or bend further at the knees.</p>	Iliopsoas
Hip Stretch	<p>Begin by lying on back, knees bent, and feet flat on the deck. Cross one leg so that the ankle is resting on the knee of the other leg. Slowly lift the one leg off the deck and move it toward the chest. The stretch should be felt in the hip of the crossed leg. NOTE: May also be performed seated using arms to pull leg, as one unit, toward body.</p>	Hip extensors
Kneeling Lunge with Pelvic Tilt	<p>Begin kneeling on deck with toes pointed straight back. Move one leg forward until knee of forward leg is directly over ankle of forward foot. Without changing position of either leg, lower front of hip downward until a stretch is felt in front of back leg. Then, perform stretch on other side. NOTE: Placing front leg slightly to the side will also stretch leg adductors.</p>	Iliopsoas

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Butterflies	<p>Begin by sitting with legs bent and bottoms of feet together. Grasp ankles and push legs to floor using elbows while bending upper torso toward feet keeping back flat.</p> <p>NOTE: Leaning upper body over one knee instead of straight ahead engages hip abductors. Bend from hips and not the back.</p>	Hip/thigh adductors
Groin Stretchers	<p>Begin standing erect, with legs far enough apart to allow for sufficient stretch, and toes pointed slightly outward. Shift body weight to one side while bending the leg on the same side. The knee of the bent leg should always be aligned over the toe to avoid stress in the ligaments and menisci of the knee joint.</p>	Hip/leg adductors
Legs		
Standing or Prone Quad Stretch	<p>While standing, bend one leg back toward buttocks stretching front of bent leg. Use hand on same side as bent leg to hold stretch. Tilting pelvis forward will engage hip flexor. Knees should be kept parallel, underneath hips. This exercise may also be performed while lying face down (prone) on deck.</p>	Leg extensors and hip flexors
Shin/Quad Stretch	<p>Begin kneeling on deck, toes pointed straight back, palms on deck. Slowly lower hips toward heels until tightness is felt in quads and shins. If unable to rest hips on heels, place hands on outside of legs and support body weight with arms. If more stretch is needed, place hands behind feet and lean slightly back, supporting body weight with arms.</p>	Shins, ankles, and quadriceps

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Hurdlers Stretch (Quadriceps)	<p>Sit with one leg bent and tucked under hips so that heel lies just outside hip; the other leg may be bent or straight. Foot should be extended straight back (not flared out to one side). Slowly, lean back until stretch is felt in top of bent leg.</p> <p>NOTE: To stretch upper thigh and hip flexors, tighten buttocks and lift hips on side of leg that is tucked under while performing this stretch. Bending front leg can provide a further stretch.</p>	Quadriceps
3 Way Hurdler's Stretch - (Hamstring)	<p>From a sitting position, extend one leg out while tucking other in front of hips with knee pointing outward. Bend torso forward toward deck keeping back straight, stretching muscles of inner thigh. Hold stretch and return to starting position. Next, turn torso toward knee of extended leg, and bend over from waist. Keeping back straight, bring chest toward knee while stretching muscles in back of leg. Return to starting position. Using arm opposite extended leg reach up and over while bending body to side. Keeping back straight, bring shoulder toward knee while reaching with opposite arm toward foot of extended leg. Stretch should be felt on side of torso and hamstrings.</p>	Leg flexors, leg adductors, and side of body
Seated Head to Knee (Sitting Hamstring)	<p>From a sitting position, extend the legs forward and bend the torso toward the knees, stretching the back of the legs. Keep knees slightly bent and the back flat throughout.</p>	Leg flexors

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Supine or Sitting Hamstring	<p>Begin by lying with back flat on deck (supine), legs extended. Bring one leg toward chest grasping ankle with 1 hand and outside of knee with other hand. Pull leg toward chest until a stretch is felt in back of leg. This exercise may also be performed sitting. Keeping back straight, bring knee of one leg toward chest. Grasping ankle with one and outside of knee with other, extend leg until a stretch is felt in hamstrings.</p>	Leg flexor
Achilles Stretch	<p>Kneel on deck, toes pointed straight back, palms on deck. Bring hips back toward heels supporting body weight with arms if necessary. Bring one foot forward until toes are parallel to knee of other leg. Let bent heel come off the ground an inch or so. Lower heel of forward leg toward ground while pushing forward on thigh with chest and shoulder. Perform stretch on other leg. Goal is not to flatten heel on deck, but rather to use forward pressure of chest and shoulders on thigh to slightly stretch Achilles tendon.</p>	Achilles tendon
Soleus Stretch	<p>Standing on a tilt board, on edge of a stair, or curb, flex foot stretching calf muscles. Bending knee of leg being stretched will engage soleus. Note: soleus and gastrocnemius comprise the calf musculature.)</p>	Soleus

Table 7-2. Static Stretch Exercises to be Used in Physical Training

Name	Description	Muscle Group(s)
Gastroc Stretch	Standing on a tilt board, on edge of a stair, or curb, flex foot stretching the calf muscles. Keep leg of stretched muscle straight.	Gastrocnemius
BUD/S Knee (ITB Stretch)	Perform while seated, with one leg extended, and other leg crossed over extended leg at knee. Turn upper torso toward bent leg, stretching iliotibial band (ITB) of that leg. Use elbow on side of straight leg to hold stretch.	Trunk and iliotibial band

A Post-Exercise Total Body Stretching Program

A suggested post-exercise total-body stretching program is outlined in Figure 7-5. Stretches are grouped by the position in which they are performed. To make the most efficient use of time, perform stretches in the sequence provided. The outlined program takes ten minutes if stretches are held for 15 seconds and performed once on each side of the body. Ideally, stretches should be performed twice on each side of the body.

Figure 7-5. Total Body Post-Exercise Stretching Program

1. Standing

Lateral/Forward Neck Flexion
Upper Back Stretch
Posterior Shoulder Stretch
Overhead Side Stretch
Triceps Stretch (and side bend)

3. On Back

Supine Back Stretch
Hip Stretch
Hip Cross-Overs

5. Kneeling

Shin-Quad Stretch
Achilles Stretch
Forearm-Wrist Stretch
Kneeling Lunge with Pelvic Tilt

2. Sitting

Swimmers Stretch
ITB Stretch
Butterflies
3-Way Hurdler's Stretch
Seated Head to Knee Stretch

4. On Stomach

Prone Quad
Torso Prone Stretch

6. Standing

Iliopsoas Stretch
Gastrocnemius Stretch
Soleus Stretch

Chapter 8

Calisthenics

Calisthenics are a traditional and integral part of the SEAL's training program because they require minimal equipment and can be performed in almost any location. Calisthenic exercises, depending on how they are performed, can be used to develop flexibility, muscle strength, muscle endurance, and/or muscle power. These terms have been previously defined in Chapter 1. In this chapter we will discuss the benefits and proper use of calisthenics within the Special Warfare training environment.

The Muscle Strength-Endurance Continuum

Muscle strength and muscle endurance exist on a continuum. Given that muscle strength is the amount of force generated by one repetition and muscle endurance is the ability to exert force repeatedly over time, improving muscle strength will improve muscle endurance. If your one repetition maximum weight is increased, your submaximum multiple repetitions can be performed with more weight (resistance).

Muscle strength is developed by performing low-repetition (6-12), high-resistance exercises. When more than 12 repetitions can be performed, the resistance should be increased, and the repetitions decreased. Muscle endurance is developed by high-repetition (>12), low-resistance exercises.

A set for an exercise is the number of repetitions performed per unit weight.

Increasing the number of repetitions per set develops endurance. For example, if an individual can perform only 10-12 sit-ups using proper technique, the exercise will develop muscle strength. Once an individual can perform over 15 repetitions per set, muscle endurance is being developed. Table 8-1 outlines the strength-endurance continuum and illustrates the training schedules used to develop various degrees of endurance. Note that strength and short-term efforts have no effect on aerobic capacity because the aerobic/endurance system is not recruited with maximal or heavy loads. In contrast, sustained efforts with a light load recruit the aerobic system and have minimal effect on strength. Generally, activities of longer duration require more muscle endurance. SEALs should modify their training programs according to the principles of strength and endurance specific to mission requirements.

Table 8-1. The Strength-Endurance Continuum

	STRENGTH	SHORT-TERM EFFORT	INTERMEDIATE EFFORT	SUSTAINED EFFORT
Goal	Maximum force 3 sets 3 times/week	Endurance with heavy load 3 sets 3 times/week	Endurance with intermediate load 2 sets 3 times/week	Endurance with light load 1 set 3 times/week
Recommendation	6-10 RM*	6 - 12 RM	12-50 RM	Over 100 RM
Enhances Strength	Muscle contractile proteins: actin and myosin; connective tissue	Some strength; anaerobic metabolism	Some aerobic and anaerobic metabolism; slight strength improvement	Aerobic enzymes; fat utilization
Does Not Alter	Aerobic Capacity	Aerobic Capacity		Strength

* RM = Repetitions Maximum Effort

Modified from Sharkey, BJ: *Physiology of Fitness*, 3rd Ed. Champaign, IL: Human Kinetics, 1990, p 91.

In general, calisthenics develop muscle endurance. There are two occasions, however, when calisthenics develop muscle strength. The first occasion depends on individual fitness level and how many repetitions can be performed. Individuals who can only perform a low number of repetitions of a calisthenic exercise (less than 10-12) will develop muscle strength. Those who can perform a higher number (more than 10-12) will develop muscle endurance. For example, when you first start doing pull-ups you may only be able to perform 9 repetitions. At this point, you are developing muscle strength. As your performance improves, and you are able to perform over 12 repetitions, you begin to develop muscle endurance.

The second occasion occurs where calisthenics are modified to overload the muscles so that they contribute to strength development. This can be achieved by any of the following:

- ◆ Adding weight (e.g., pull-ups or push-ups while wearing a weighted pack).
- ◆ Using a buddy for resistance (e.g., having a buddy sit on your hips while doing bent over calf raises; buddy- assisted leg extensions).
- ◆ Exercising on one side of the body only (e.g., one-legged squats or calf raises).
- ◆ Modifying the exercise (e.g., elevating the legs during push-ups).
- ◆ Super sets/pyramids.

These modifications can be particularly helpful if weight training facilities are not available and a strength workout is required.

Calisthenics in Naval Special Warfare

Muscle strength and endurance are both essential for operational performance. Muscular strength is also required for many Special Warfare missions. Muscular endurance is needed when work is required over longer periods of time (e.g., patrolling with a heavy load, climbing with equipment, swimming, or carrying a buddy).

The goal of a physical training (PT) program for the SEAL should be to develop complete muscular fitness (i.e., strength, endurance, and power). Muscle strength provides the foundation for muscle endurance and power. An adequate strength base not only improves performance, but also decreases the likelihood of injury. For this reason it is recommended that at least two strength workouts (low-repetition [10-12 reps], high resistance exercises per muscle group per week), as described in Chapter 6, be part of the SEAL's physical fitness program. Traditional calisthenic exercises performed two to three times a week will develop and maintain muscle endurance. A plyometric program (See Chapter 9) when necessary, can also be used to develop muscle power.

Mission-related training schedules, lack of exercise equipment, and inadequate nutrition can keep operators from maintaining required fitness levels in the field. Calisthenics, however, are practical for field situations because they can be performed anywhere with minimal equipment. Moreover, calisthenics can also be modified to provide a strength workout.

A unit's PT schedule should be flexible enough to accommodate different training needs.

It may take one to four weeks for an operator or platoon returning from the field to completely regain levels of aerobic and muscular fitness comparable to those when exercising regularly in a basic unit PT program. Allowing time to gradually increase fitness will improve performance, prevent overtraining, and decrease the likelihood of overuse injury or re-injury. Those returning to PT following surgery and/or rehabilitation need to return to basic PT gradually. When performing calisthenics, **more is not necessarily better**, and in fact, can be harmful. Too many repetitions can cause an overuse injury or worsen an existing injury.

The goal of a PT program should be to develop aerobic capacity, muscular strength, endurance, power, and flexibility, NOT TO OUT PERFORM OTHERS.

Competitive exercise situations, such as “Burn Out” PT and pyramid sets, can be challenging, but if not handled correctly, can cause injury. SEALs should train like elite athletes and avoid situations that could contribute to injury.

Calisthenic sessions occasionally include holding an exercise in the halfway position for 2-10 seconds. This technique is often applied to pull-ups, dips, or push-ups in an attempt to make the exercise more difficult or alleviate boredom. For example, when performing a pull-up, the operator will maintain the position halfway between the starting position and the bar, while the chin is over the bar, and again halfway down the bar. This technique is NOT recommended.

Holding a mid-exercise contraction stresses the joints, tendons, and ligaments and can cause an injury or worsen an existing injury.

Slowing the cadence throughout the entire exercise (i.e., 10 seconds up to the bar, 10 seconds back to the starting position), is recommended for added strength gains, alleviation of boredom, or to increase the difficulty.

Balancing Abs and Hip Flexors and Extensors

Many calisthenics, performed to strengthen the abdominal (Abs) muscles, are actually exercises for the hip flexors (muscles that move the hips and legs toward the chest). This causes over-development of the hip flexors and under-development of the abdominals. Although both hip flexor and abdominal strength is necessary for operational performance, overdeveloped hip flexors play a significant role in the development of lower back problems. Overdeveloped hip flexors not only change the curvature of the spine, but also stress the front portion of the vertebral discs. **Many experts contend that much of the low-back pain in the SEAL community is due to an overabundance of hip flexor calisthenics.** Hip flexor strength is necessary, but it should be balanced with equally developed strength and flexibility in the hip extensors (muscles which move the legs away from the chest) and abdominals.

A balanced workout incorporates abdominals, hip flexors and hip extensors.

Therefore, it is important to identify which exercises are appropriate for each muscle group (i.e., abs, hip flexors, hip extensors) and include all three in a PT program. A calisthenic program should also incorporate a flexibility program in order to prevent the exercised muscles from becoming too tight (see Chapter 7: Flexibility).

Exercises that anchor or elevate the legs and feet off of the deck (e.g., Hello Darlings, Flutter Kicks, Leg Levers, Inboard Outboards) are actually working the hip flexors. When performing these types of exercises, the torso and upper abdominals act to stabilize the pelvis during the movement. For this reason it is suggested that **hip flexor exercises be performed first**. Exercising the abdominals first causes them to become fatigued and therefore unable to stabilize the pelvis. The following recommendations will strengthen the abdominals:

- ◆ Identify exercises which are true abdominal exercises versus those which work the hip flexors.
- ◆ Decrease the number of hip flexor exercises performed to two sessions per week with fewer repetitions per session.
- ◆ Increase the number of true abdominal exercises (e.g., Crunches, Elbow to Knee/Cross Overs, Hip Rollers, Side Flex). Abdominal exercises can be performed daily or as limited by muscle soreness.
- ◆ Add hip extensor exercises (e.g., Prone Back Extension, The Superman, Donkey Kicks).

- ◆ Incorporate a total body flexibility program into Special Warfare training and include stretches for the hip flexors, abdominals, and hamstrings.
- ◆ Focus on proper technique as presented below.

Proper technique is important when performing all calisthenics.

If the muscles are not strong enough to perform an exercise properly, other muscles will come into play. The result: the wrong muscles get developed and can lead to injury. For example, exercises that are too difficult for the lower abdominals will rely on the hip flexors. Hip flexors which are relatively stronger than the abdominals, result in the stomach protruding. This may lead to injury and low-back pain. Proper technique is essential.

The following suggestions should decrease mechanical stress on the low back during hip flexor exercises:

- ◆ Keeping one foot on the deck minimizes the stress placed on the lower back and spine. Many exercises that require both legs to be off the deck simultaneously can be modified so that one foot is constantly on the deck supporting the low back (Figure 8-1 and Figure 8-2).
- ◆ Placing a fist under the lower part of the buttocks helps to keep the spine in a neutral position.
- ◆ Lifting the head and slightly rolling the shoulders helps maintain the position of the spine.
- ◆ Performing hip flexor exercises prior to abdominal exercises.

Figure 8-1. Modified Flutterkick: Keeping One Foot on the Deck Protects the Lower Back

**Figure 8-2. Modified “Knee Bender”:
Keeping One Foot on the Deck Protects the Lower Back**

Another change that should be incorporated in an abdominal workout is the addition of a 2 inch thick towel or an “Ab Mat” beneath the lower spine. The anatomical range of motion for the abdominals is from 30° extension to approximately 75-90° flexion (Figure 8-3). When performing abdominal exercises on a flat surface (i.e., the deck) you are limiting your exercise to only half the normal abdominal range of motion. In other words, when abdominal exercises are performed on a floor, deck, or mat, only half the work necessary to develop abdominal strength is being done. Abdominal strength is best developed by exercises performed within the full anatomical range of motion, with some curve in the lumbar spine (i.e., towel or Ab Mat) as opposed to a flat back. By placing a towel or the Ab mat beneath your lower spine you can achieve the right form for these exercises (see Figure 8-4).

Figure 8-3. Range of Motion for Flexion and Extension of the Upper Body Based on Anatomy

Figure 8-4. Placing a Towel Beneath the Lower Spine can Help Achieve the Right Form for Abdominal Exercises

Because of limited flexibility, it is better to start abdominal exercises at approximately 15° of extension and eventually work toward 30° extension. A towel is particularly useful because you can adjust it to provide inclines of 15° and 30°.

Recommendations for Sit-Ups

In recent years, the sit-up technique has undergone many modifications. Because sit-ups compose a large portion of the SEAL training program, some specific comments regarding their proper use are crucial.

When performing sit-ups, the preferred technique is to bend the legs at the hips (at 45°) with the feet flat on the deck shoulder width apart. Legs should be slightly abducted (turned outward). If hands are placed behind the head, care should be taken not to force the

neck into flexion. The fingertips of the hands should just barely touch the back of the head. Elbows should remain back at all times. Concentration on using the abdominals (not the head) to pull through the movement is essential. Keeping the eyes focused on the ceiling helps prevent neck strain and isolate the abdominals. Lifting the torso until the shoulder blades come off the floor engages the majority of the abdominal musculature. Lifting the torso further off the deck will safely engage the internal obliques and the hip flexors, if that is the goal (see Figure 8-5).

Figure 8-5. Proper Technique for Sit-ups: Legs Slightly Turned Outward and Elbows Behind Neck at All Times

When first performing the sit-up from an extension position, you may not be able to perform as many repetitions. This should not be surprising since essentially, you have been performing only half a sit-up in the past.

The focus should be on the quality, not the quantity, of sit-ups.

The same principles that govern the muscle strength-endurance continuum apply to the abdominal musculature. The muscular fitness component you will develop (i.e., strength vs. endurance) is determined by the number of sit-ups performed using a towel or “Ab Mat” beginning with 15° of extension. If muscle strength is the goal, you may want to move to 30° extension. Once you are performing over 15 reps per set at 30° extension, you can increase the difficulty of the exercise by changing the position of the arms, adding weight, or performing sit-ups on a decline. Variations in arm positioning, from the easiest to the most difficult, are shown in Figure 8-6:

- ◆ At the side of the body.
- ◆ Across the chest.
- ◆ Behind the head.
- ◆ Clasped together above the head; weight can be added for more resistance.

Figure 8-6. Variations on Sit-Up Routines

Arms at Sides

Arms across Chest

Arms behind Head

Arms above Head

If the goal is to develop muscle strength, enough resistance should be added to keep the repetitions per set below 15. Once there is a sufficient foundation of muscle strength, muscle endurance can be developed. As with calisthenics, when muscle endurance is the goal, enough weight should be added to keep the repetitions between 15-50 per set. These principles apply to all other types of sit-ups as well (i.e., Crunchers, Vee-Ups, Cross Overs).

Recommendations for Calisthenics

Two evolutions per week on nonconsecutive days are recommended for calisthenic (muscle endurance) training. Additionally, weekly PT sessions using the calisthenic modifications for muscle strength are recommended. Calisthenics may be performed in conjunction with plyometrics, strength training, or aerobic training. Static stretches for specific body areas may be performed (filler stretches) once the workout for that area of the body is complete; however, a significant drop in exercise tempo should be avoided in order to keep exercising muscles warm.

For a 30-minute workout, choose 1 to 3 exercises from each of the following categories. For a 60-minute workout, choose 3-6 exercises from each of the following categories. Remember to balance the front of the body with the back (e.g., hip flexors/abdominals with hip extensors, quadriceps with hamstrings, hip adductors with hip abductors). The resting period between exercises may vary depending on individual or group fitness level.

Calisthenic Exercises

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Overall Exercise		
Jumping Jacks	<p>A 2-count exercise from a standing position with feet together and hands at sides. Count 1: jump up while bringing hands together over head and landing with feet shoulder width apart. Count 2: jump back to starting position</p> 	Aerobic: A good warm-up exercise
Eight-Count Body Builders	<p>An 8-count exercise from a standing position. Count 1: bend legs and place hands on deck. Count 2: extend both legs backward supporting body weight with extended arms (starting position for a push-up). Count 3: bend elbows, lowering chest toward deck (a push-up). Count 4: extend arms. Count 5: separate legs while keeping arms extended. Count 6: bring legs back together as on count 4. Count 7: flex legs and bring them back to count 1 position. Count 8: stand and return to starting position.</p> 	Chest and leg muscles

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Neck Exercises		
Neck Rotations	A 4-count exercise. Begin lying on back. Count 1: lift head up and over to side. Count 2: lift head straight up; Count 3: bring head to other side. Count 4: head returns to starting position. Can also be performed on stomach facing deck in order to condition neck extensors.	Neck flexors and extensors
Chest, Shoulders, and Arms		
Triceps Push-Ups	<p>A 2-count exercise. Begin by lying on stomach, with feet and hands on deck, fingers spread, thumb and index fingers on both hands almost touching each other, elbows extended, and body straight. Count 1: bend elbows at least 90° using arms to support body weight. Count 2: return to starting position.</p> 	Triceps and muscle groups used in regular push-ups
Push-Ups Wide, Standard, and Narrow	<p>A 2-count exercise. Begin lying on stomach with hands and feet on deck, arms extended, and head facing forward. Count 1: bend elbows to at least a 90° angle, lowering chest toward deck. Count 2: extend arms back to starting position. Should be performed first with hands placed wider apart than shoulder-width (Wide Push-Ups), then, gradually move hands closer together so that smaller muscles (i.e., triceps) are worked last. Starting wide minimizes problem of fatiguing triceps before pectorals.</p> 	Chest, anterior shoulder, triceps and abdominal muscles

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Dive Bomber Push-Ups	<p>A 2-count exercise. Start by assuming a leaning rest position with feet spread ~ 3 ft. apart, palms on deck, elbows fully extended, and hips slightly lifted. Count 1: upper torso sweeps down toward deck between and through hands while bending elbows. Resting position is same as down position of basic push-up. Count 2: upper torso sweeps back and up while elbows extend to return to starting position.</p> 	Chest, forearms, triceps, and anterior deltoids
Finger-Tip Push-Ups	<p>A 2-count exercise: Perform same as a regular push-up, but support weight on fingertips.</p> 	Forearm and muscle groups used in regular push-ups. Good for forearm and grip strength

Back

Training Tip: Putting tape around pull-up bar or using wider pull-up bars will develop more grip strength. Many athletes have difficulty transferring strength gains achieved during exercise into actual performance gains because many of the movements performed during sports are done with a more open-handed grip. This is particularly relevant to the SEAL community where many of the movements necessary for operational performance require a more open-handed grip (i.e., lifting yourself up and over a barrier). Adding a piece of athletic tape to pull up bars with each successive workout (i.e., gradually increasing the thickness of the bar) steadily develops open-handed grip strength.

Dips	A 2-count exercise which requires use of parallel bars. Flex and extend arms while supporting body weight.	Triceps, back, and to some extent, chest and shoulder muscles
------	--	---

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Chin-Ups	<p>A 2-count exercise beginning at a dead hang (i.e., full extension) from a horizontal bar with arms shoulder-width apart and palms facing inward. Pull body upward on count 1 until chin touches top of bar. Return to starting position on count 2. No kicking or kip-up allowed.</p>	<p>Back and bicep muscles</p>
<p>Pull-Ups (Wide, Standard, Narrow, Behind the Neck, Interlocking)*</p>	<p>A 2-count exercise beginning at a dead hang from a horizontal bar with arms shoulder width apart and palms facing outward. Pull body up on count 1 until chin touches top of bar. Return to starting position on count 2. No kicking or kip-up allowed.</p>	<p>All muscles of back and forearm (Especially good for grip strength)</p>
Incline Pull-Ups	<p>A 2-count exercise. Requires a low bar (i.e., a dip bar). While lying or sitting on ground (depending on how low bar is), grab bar with both hands and pull upper body toward bar at a 45° angle. Emphasis: pulling shoulder blades together during movement.</p>	<p>Posterior shoulder muscles and triceps (Need to balance extensive # of push-ups in SEAL training.)</p>

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Abdominals		
These exercises will help develop abdominal strength.		
Vee-Ups	<p>A 2-count exercise. Lie on back with arms behind head, legs vertical. Lift arms and upper torso toward feet. Only upper torso should elevate off deck.</p> <p>Variations: Keep upper body on deck with arms to sides and legs vertical. Lift only hips off ground a few inches as if pushing feet toward ceiling. This movement, although small, burns after only a few reps.</p>	Abdominals
Crunches	<p>A 2-count exercise. Start by lying on back with legs bent and elevated off deck and placing hands behind head. Lift upper torso 10 to 12 inches off ground, then return to starting position.</p> <p>Variations: legs may be bent with feet on deck, bent with knees toward chest and feet elevated, or extended vertically (as in Vee-Ups). Arms may be placed in several positions (easy to most difficult): alongside body, across chest, hands behind head, or hands clasped above head. Adding a pelvic tilt at peak of abdominal contraction engages lower abdominals.</p>	Abdominals
Sit-Ups	<p>A 2-count exercise. Described in detail above. Ideally, should be performed within full range of motion (30° extension to 75°-90° flexion), but may be performed so that upper or entire torso is lifted off floor. Lifting only upper torso will engage most abdominals; lifting entire torso will engage internal obliques and hip flexors.</p>	Abdominals

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Elbow to Knee/ Cross Overs	<p>A 2-count exercise. Lie on back with hands clasped behind head. Legs can be bent at knees (feet on deck), with one leg crossed over knee of opposite leg or bent with knees toward chest (feet elevated from deck). Slowly lift and twist torso bringing one shoulder toward knee of opposite leg. Engaging obliques requires rotation to start immediately at beginning of exercise, not at top. Return to starting position. Perform exercise by turning torso to both left and right knees.</p>	Abdominals and obliques
Hip Rollers	<p>A 2-count exercise. Lie on back with legs bent and elevated off deck, slowly bring both knees down together on one side until low back begins to lift off deck. Bring knees back to starting position, then repeat on other side.</p>	Abdominals
Abdominals and Hip Flexors		
Good Morning Darlings	<p>A 2-count exercise. Lie on back with palms on deck and hands under hips, legs extended, and feet together, 6" above deck. Count 1: spread legs 2-3 feet apart. Count 2: bring legs back together.</p>	Abdominals and hip flexors

Note: These exercises should be limited to twice per week to prevent over-development of hip flexors. Proper technique is essential; performing these exercises improperly can contribute to or worsen low-back pain.

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Flutter Kicks	<p>A 4-count exercise. Lie on back with hands under hips, legs extended, and feet together 6" above deck. Count 1: lift right leg 1 1/2 feet, keeping leg straight. Count 2: lift left leg to same position while returning right leg to starting position. Count 3: bring right leg back up and return left leg to starting position. Count 4: repeat.</p> 	Abdominals and hip flexors
Sitting Flutter Kicks	A 4-count exercise. Flutter Kick performed from a seated position.	Abdominals and hip flexors
Knee Benders (Supine and Seated)	<p>A 2-count exercise. Lie on back with arms at sides. Bring both legs 6" off deck, bend at knees, bringing legs toward chest. Straighten knees and lower legs down again. Variation 1: Perform same leg movements from a seated position. Variation 2: Begin with hands clasped behind head, one leg bent with foot on deck, and other leg extended. Bend extended leg, keeping foot off deck, and bring it toward chest while lifting shoulders off deck. Return to starting position.</p>    <p>Variation 1</p>  <p>Variation 2</p>	Abdominals and hip flexors

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Inboard/Outboards	<p>A 2-count exercise. Lie on back, hands under hips, feet 3 feet apart and 2 feet above deck. Make small circles by bringing feet out, around, up, in, and down: inboard circles. Change directions for outboards.</p>	 <p>Abdominals and hip flexors</p>
<p align="center">Back and Hip Extensors</p>		
The Superman (Prone and Kneeling)	<p>A no count exercise. Either lie on stomach or on hands and knees. Opposite arm and leg (i.e., right arm, left leg) should be lifted and held for 3 to 5 seconds, then slowly lowered. Same movements should then be made with other arm and opposite leg. Superman can be made more difficult by adding weights to arms and legs. To avoid hyperextension of back, leg should not be raised higher than hip when in kneeling position.</p>	 <p>Back muscles and hip extensors (Helps develop balanced strength between hip flexors and hip extensors. Very safe, but can burn after a while.)</p>
Donkey Kicks	<p>A 2-count exercise. On hands and knees, extend one leg out and behind, then bring it back. Repeat this movement using the same leg until a burn is felt in the hips and lower back. Then exercise the opposite leg. To avoid hyperextension of back, the leg should not be raised above hip.</p>	 <p>Hip extensors</p>

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Prone Flutter Kicks	<p>A 2-count exercise. Flutter Kick performed lying on stomach. Avoid hyperextension of back.</p> 	Back and hip extensors (Highly recommended; helps balance hip flexor conditioning.)
Prone Back Extension	<p>A no count exercise. Lie face down on deck, hands clasped behind back, lift upper torso off deck, hold, and return to starting position. Avoid hyperextension of back. Placement of hands alters difficulty; behind back is easiest, behind head is more difficult, straight out in front is most difficult.</p> 	Back and hip extensors

Hip/Leg Abductors and Adductors

Note: It is highly recommended that exercises for both leg abductors (i.e., muscles that carry leg away from body) and leg adductors (i.e. muscles that bring leg toward body) be added to the special operations PT program. No exercises that effectively exercise these muscle groups are currently used in team PT sessions.

Leg Lifts	<p>Lie on side: bend legs at a 90° angle from torso. Lift and lower top leg. Knee and ankle should always be in the same plane. Weights can be added to legs if more resistance is needed.</p>  <p>Variation 1: 4-count exercise: on count 1 lift leg; on count 2 extend leg while elevated. Count 3: bend leg and return to count 1 position. Count 4: return leg to starting position.</p>	Hip and thigh abductors
-----------	--	-------------------------

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
Burt Reynolds	<p>A 2-count exercise. Lie on side with head supported by hand. Bend top leg and place it in front of the knee of opposite leg. Raise and lower straight leg approximately 8" off deck until fatigued. Should be felt in inner thigh and balances hip abductor exercises.</p>	<p>Hip adductors. Beneficial for rock climbing</p>
Other Leg Lift Variations	<p>Variation 2: On count 4 do not return leg to starting position, but keep leg elevated while extending then flexing leg until a burn is felt in hip. Lift and lower top leg.</p> <p>Variation 3: Keep bottom leg at 90° angle while keeping top leg straight. Top leg should remain aligned along bottom leg.</p> <p>Other Variations: Use foot to draw circles in the air; Keep leg elevated, and move foot toward head and back; Make an arch in air so big toe touches ground above knee then below.</p>	<p>Hip and thigh abductors</p>

Leg Muscles: Extensors and Flexors

Hand to Knee Squats	<p>A 2-count exercise. Feet flat on deck, shoulder width apart with arms relaxed at sides. Keep back straight, and feet flat, bend at knees until your fingertips pass knees, then return to starting position.</p>		<p>Hip and leg thigh muscles</p>
---------------------	---	--	----------------------------------

Table 8-2. Recommended Calisthenics for Physical Training

Name of Exercise	Description of Exercise	Muscle Group(s)
One-Legged Squat	<p>A no count exercise. Use one leg to support body weight: bend leg until thigh is almost parallel to ground and return to starting position. Repeat using other leg. Squat should not pass position where upper portion of legs are parallel with ground. Going lower places excessive stress on knee.</p> 	Hip and thigh muscles (Useful when equipment and/or weights are not available.)
Lower Leg Muscles		
Calf Raises	<p>A 2-count exercise. Standing on deck or surface (e.g., a curb) which allows heels to hang over side. Raise and lower body weight by raising and lowering heels no more than 3 inches. Perform exercise with toes pointed inward, straight, and turned outward.</p> 	Calf muscles

Modified Calisthenic Exercises

Calisthenic exercises can be modified to provide a strength workout by increasing resistance, using a buddy, or some other source of added weight. Many experts recommend buddy-assisted exercises for the following reasons:

- ◆ Can be performed in any location with no equipment.
- ◆ Help to maintain strength base in the field.
- ◆ Teach reliance on another operator.

Most buddy-assisted exercises are designed to develop strength, depending on the amount of resistance one's partner applies. As with regular calisthenics, the muscle strength-endurance continuum applies. If you can only perform 4-10 reps per set, you are building strength. If you can perform over 10 reps per set you are beginning to build muscle

endurance. Depending on the fitness goal, the partner can apply as much resistance as necessary to control the number of repetitions. For maximum benefit, perform these exercises slowly. Table 8-3 provides suggestions to aid in developing a buddy-assisted exercise program.

Table 8-3. Tips for Developing a Buddy-Assisted Exercise Program

A 5-10 minute warm-up should precede each exercise session followed by stretching for the part of the body to be exercised.

Perform 6-10 reps per set. Each partner should perform 1-3 sets per exercise.

Completion of exercises for a muscle group should be followed by stretches for body area exercised.

Partners should be of similar height and weight.

Some examples of buddy assisted exercises are provided in Table 8-4. Additional exercises and illustrations can be found in Gain W., Hartmann J. *Strong Together! Developing Strength with a Partner*, 1990.

Table 8-4. Buddy Exercise Drills

Exercise	Description	Muscle Group(s)
Chest, Shoulders, Arms		
Front Push-Up	Lead partner in leaning-rest position. Support partner grabs ankles and lifts to hip level. Lead partner performs push-ups from this position. Body straight throughout.	Chest, triceps, anterior shoulder, and abdominal muscles
Push-Up Walk (Wheelbarrow)	Lead partner in leaning-rest position. Support partner grabs ankles and lifts to hip level. Lead partner walks on hands. May also be performed with arms bent.	Shoulder, chest, triceps, and abdominal muscles
Back or Side Push-Ups	Lead partner is in back or side push-up position. Support partner grabs ankles and lifts them to thigh/hip level. Lead partner performs a backward push-up with both arms or side push-up with one arm. Keep body straight throughout movement.	Back Push-Ups: back, triceps, shoulders, and muscles. Side Push-Ups: triceps, shoulders, upper back, and chest muscles
Backward Push-Up Walk	Lead partner is in Back Push-Up position. Support partner grabs ankles and lifts them to thigh/hip level. Lead partner walks backward with hands.	Shoulders, back and abdominal muscles
Handstand Push-Ups	Lead partner performs a handstand. Support partner grabs ankles to balance lead partner. Lead partner then bends and straightens arms. Do not touch head to deck.	Shoulders, chest, and triceps muscles
Resistance Exercises - Arms	Lead partner lies on back. Support partner applies resistance against movement of arms up and toward head, down and toward hips, and straight out from body. Resistance can be applied in both directions. For example, resistance can be applied against arms while they are extended outward pushing toward floor or while arms are extended outward pulling to midline. This exercise can also be performed with lead partner lying on stomach.	Shoulder, chest and back muscles

Table 8-4. Buddy Exercise Drills

Exercise	Description	Muscle Group(s)
Back		
Trunk Drops from Bench Position	Lead partner kneels with hands behind head while support partner holds ankles of lead partner. Lead partner lowers trunk until forehead touches ground and then returns to starting position.	Back extensors
Arm Raises from Bench Position	Lead partner kneels with hands extended above head while support partner holds lead partner's ankles. Lead partner then brings hands to the side and back to starting position.	Back extensors
Abdomen		
Trunk Lifts	Lead partner lies on back with hands behind head. Feet are held by support partner at hip level. Lead partner then raises and lowers head and trunk.	Abdominals
Trunk Twisters and Trunk Side Bends	Starting position is fireman's carry with lead partner carrying support partner on shoulders. With feet shoulder-width apart, lead partner twists to right and then to left. Lead partner may also bend from waist to right and to left. Be careful not to use momentum of support partner's weight to carry movement beyond a controllable range of motion.	Obliques
Hips, Legs, and Calves		
Two-Man Squat	Partners stand with backs to each other leaning into each other's weight. Simultaneously, both partners squat until thighs are parallel to floor. Both partners return to starting position keeping backs together for support.	Hips, quads and hamstrings

Table 8-4. Buddy Exercise Drills

Exercise	Description	Muscle Group(s)
One-Legged Squat	Start from standing position. Support partner holds leg and opposite arm of lead partner. Lead partner performs a squat until thigh of bent leg is parallel to ground using support partner for balance. Lead partner returns to starting position.	Hips, quads and hamstrings
Fireman Squats and Lunges (Cartilage Crunchers)	Lead partner holds support partner in fireman's carry. Using support partner's weight for resistance, lead partner performs a squat until thighs are parallel to floor and then returns to standing position. Lead partner may also perform forward and side lunges using support partner's body weight for resistance.	Hips, quads and hamstrings
Resistance Exercises - Legs	Lead partner lies with back on deck or stands. Support partner applies resistance as lead partner moves bent leg down toward floor or up toward chest.	Hips flexors and extensors
Fireman Toe Raisers	Lead partner holds support partner in fireman's carry. Using support partner's weight for resistance, lead partner raises up on toes, and then lowers himself. Should be performed with toes straight, pointed outward, and turned in.	Gastrocnemius
Push-Up/Squat	Partner 1 in leaning rest with feet resting on shoulders of Partner 2. Lead partner bends arms to a push-up position while Partner 2 bends legs to a squat position. Return to starting position at same time.	Partner 1: Chest, triceps, anterior shoulder, and abdominals Partner 2: Hips, quads, and hamstrings

Chapter 9

Plyometrics

Premature plyometric training may cause injury because plyometrics place considerable stress on the body. Plyometrics is an advanced training technique that should only be performed under the guidance of those with knowledge and experience with this type of training. It involves explosive types of activities (i.e., jumping onto and down from objects, bounding up and down stairs on one or both feet and high speed sending and receiving) to convert muscle strength to muscle power. Whenever you run, jump, catch or throw, you are performing a plyometric movement.

Box Jump

Side Cone Jumps

Plyometric exercises train the muscles to reach maximal strength in the shortest time possible. In other words, **muscle strength plus speed equals muscle power**. The rapid application of force is the goal of plyometric training. Plyometric exercises will not train an energy system as seen with aerobic or strength conditioning; rather such exercises train the *neuromuscular system* so that it may respond more quickly to increased loads. By making use of the inherent elasticity of the muscles and certain neuromuscular reflexes, plyometric exercises enhance the speed and distance an object moves (e.g., your body, shot put).

Plyometric training is very intense, highly specific, and if done improperly it may be injurious. It should not be routinely incorporated in the Naval Special Warfare physical training programs.

How Plyometrics Work

Plyometric exercises help to develop explosive strength and speed in fast twitch muscle fibers. These exercises use the inherent stretch-recoil properties of muscle (i.e., eccentric tension generated when the muscles are lengthened) to enhance subsequent shortening or concentric contractions. This is the dynamic action behind the rapid pre-stretch or “cocking” phase to “activate” these natural recoil properties. Examples of this phase include taking the arm back into position prior to throwing a baseball or bending the knees prior to jumping. Thus athletes that rely on explosive strength and speed, such as sprinters and basketball players, include plyometrics in their training programs. A plyometric movement can be broken down into three phases:

- ◆ Lengthening phase (eccentric contraction).
- ◆ Amortization phase.
- ◆ Take-off (concentric contraction).

Figure 9-1. Three Phases of Plyometrics: Lengthening, Amortization and Take-Off

During the *lengthening* phase, the muscle creates tension like a spring being stretched. This type of contraction, called an eccentric contraction, occurs when

performing movements such as jumping down from an object, running downhill, or lowering a weight. During an eccentric contraction, tension is built into the muscle as it

lengthens. The **take-off** occurs via concentric contraction of the muscles. During this phase, the muscle shortens as it contracts, and actual work (i.e., movement of the body through space) is performed.

The **amortization** phase is the period of time from the beginning of the lengthening phase to the beginning of the take-off phase. This is the most important phase when it comes to plyometric training. During this phase, the muscle must convert the muscular tension generated during the lengthening phase to acceleration in a selected direction during the takeoff phase. The elastic properties inherent within the muscles and neuromuscular reflexes (the stretch reflex) are responsible for this conversion. Plyometric training may increase the efficiency of this conversion. The goal of plyometric training is to decrease the amount of time in the amortization phase and thereby increase speed.

Preparation for Plyometric Training

Plyometric exercises should be undertaken only once an adequate strength base has been developed. Most sources define an adequate strength base for lower body plyometrics as the ability to squat or leg press 1.5 to 2.0 times your body weight for one maximum repetition. For upper body plyometrics, larger athletes (weight greater than 115 kg or 250 lbs.) should be able to bench press their body weight and athletes weighing less than 115 kg (250 lbs) should be able to bench press 1.5 times their body weight.

Plyometric training should never be undertaken if you have any leg, hip, arm, or shoulder injury.

Safety in Plyometric Training

Several steps can be taken to ensure that plyometrics training is safe. These measures include using an appropriate surface, footwear, and equipment, and proper technique.

Surface

Plyometrics should not be performed on hard surfaces such as concrete or steel, nor should they be performed on soft surfaces such as sand. **The best surface is a grass field, followed by artificial turf or wrestling mats.** Wrestling mats should not be too thick (> 15 cm) since they will increase the time in the amortization phase. The stored energy gained during the lengthening phase will be lost, and this will defeat the purpose of plyometric training.

Footwear

Recommended shoes are those that provide ankle and arch support, lateral stability, and have a wide, non-slip sole.

Equipment

Boxes that are used for in-depth or box jumps should have a non-slip top and should never exceed a height of 1.2 m (0.5 - 0.75 m is recommended: 1.5 to 2.5 ft. and less than 4 ft.).

Medicine balls are commonly used for many of the exercises. This is a ball that weighs no more than 10% of your typical training weight. For example, if you regularly train with a 200 pound bench press, then the medicine ball you use should be no more than 20 lbs. These balls can be covered with leather, plastic, rubber, or any type of fabric.

Technique

As with other exercises, attention should be paid to proper technique. For example, when performing lunges, the knee angle should not exceed 90°. Any movement beyond this angle will place undue stress on knee cartilage and ligaments. Keeping the knee directly over and in line with the big toe will help maintain technique. The step should be straight out, not to the side. The shoulders should always be over the knees during landing when performing in-depth jumps.

Fatigue from high-volume training can compromise technique and result in injury. When technique begins to fail, it is time to stop the exercise and rest.

Program Design and the Overload Principle

Plyometrics training should be tailored to account for individual characteristics and the activity for which one is training. More stress will be placed on the muscles, joints, and connective tissue of heavier individuals, therefore, bigger operators (weight greater than 90 kg or 198 lbs.) should not perform high-intensity plyometric exercises. **Persons with a previous history of injury should be cleared by a medical officer prior to plyometric training.** As previously stated:

Persons with any type of musculoskeletal injury should not consider plyometrics training.

A plyometrics program for the special operations community should incorporate those types of movements (i.e., linear, vertical, lateral, or a combination) required for operational performance. For example, downhill skiing would require diagonal movements, close-quarters battle (CQB) would require horizontal, vertical, and diagonal movements.

The overload principal is the basis for any training program whether it be cardiovascular training or the development of muscular strength, endurance, or power. The three basic variables used in the overload principal include the frequency, volume (or duration), and intensity of training. By increasing any one or a combination of these variables within a training program, one can continuously and safely overload the system that is to be trained (i.e., cardiovascular, muscular, neuromuscular).

Frequency

Frequency is the number of workouts per week (or other unit of time). For plyometric training, the range is usually from one to three sessions per week, depending on the sport and season. A plyometric training program for the Naval Special Warfare community should consist of two training sessions per week when operational demands require such training. Allow 2-3 days for recovery between workouts to avoid overtraining or injury.

Volume or Duration

The volume for plyometric training is defined as the number of foot contacts or landings per session.

- ◆ Beginners: 80-100 landings per session.
- ◆ Intermediate: 100-120 landings per session.
- ◆ Advanced: 120-140 landings per session.

Intensity

The intensity for plyometrics training is the level of stress placed on the neuromuscular system, the connective tissue, and the joints, and is determined by the type of exercises performed. For example, skipping is a low intensity exercise while in-depth box jumps are of higher intensity. Some guidelines are provided as follows:

- ◆ Vertical jumps are more stressful than horizontal jumps.
- ◆ One leg landings are more stressful than landings on two feet.
- ◆ The higher off the ground the body, the more forceful the landing and the more stressful the exercise.
- ◆ Adding external weight to the body also increases the stress.

When designing a program, it is best to increase only one variable per session to reduce the likelihood of injury. Generally frequency is held constant while either the volume or the intensity is increased. In advanced plyometrics, when high intensity exercises are performed, volume should decrease since these exercises place significant

stress on the muscles, joints, and connective tissue. Table 9-1 provides an example of a 10-week progressive plyometric program. Remember: exercises that mimic the activity to be performed during the mission task should be selected.

Table 9-1. A 10-Week Plyometric Program

Weeks	Exercises	Volume
Weeks 1 and 2	4 Low Intensity	10 Reps: 2 Sets
Weeks 3 and 4	2 Low and 2 Medium Intensity	10 Reps: 2 Sets
Weeks 5 and 6	4 Medium Intensity	10 Reps: 2-3 Sets
Weeks 7 and 8	2 Medium Intensity and 2 High Intensity	10 Reps: 2-3 Sets 10 Reps: 2 Sets
Weeks 9 and 10	4 High Intensity	10 Reps: 2 Sets (Box Jumps)

Adapted from "Speed Development and Plyometric Training" by W. B. Allerheiligen, In: TR Baechle (Ed). *"Essentials of Strength Training and Conditioning"*, National Strength and Conditioning Association Champaign, ILL. Human Kinetics, (pp. 314-344), 1994.

Table 9-2 classifies plyometric exercises by their jump direction and intensity level. This table can be used in combination with Table 9-1 to develop a specific plyometric program. All exercises are described in detail in the following section.

Table 9-2. Plyometrics: Classified by Jump Direction and Intensity

Direction	Low Intensity	Medium Intensity	High Intensity	Shock
Vertical	Squat Jump, Split Squat Jump, Cycled Split Squat Jump	Pike Jump, Double Leg Tuck Jump	Double Leg Vertical Power Jump, Single Leg Vertical Power Jump, Single Leg Tuck	In-Depth Jump, Box Jumps (Single or Double)
Horizontal with a Vertical Component		Standing Triple Jump, Double Leg Hop, Alternate Leg Bound, Combination Bound, Front Hurdle Hops	Single Leg Hop	
Horizontal		4 Line Hop Drill	Double Leg Speed Hop, Single Leg Speed Hop	In-Depth Jump, Box Jumps
Diagonal		Double Zig-Zag Hop, 4 Line Hop Drill		
Lateral		Side Hurdle Hops		
Upper Body Plyometrics	Forward Ab Throw, Medicine Ball Chest Toss, Side Ab Throw, Medicine Ball Sit-Up, Plyometric Sit-Up	Medicine Ball Push-Up	Push-Up with a Clap	Drop Push-Up

Plyometric Training

Plyometric training should begin with a general warm-up followed by dynamic stretching (see Chapter 7 for stretching). Stretches should mimic the activity to be performed (e.g., 4-Way Lunges and Leg Swings for lower body plyometrics; Up Back and Overs or Press-Press-Fling for upper body plyometrics). Static stretches can also be added.

Two sessions of plyometrics per week is sufficient for SEALs.

This statement is true when operators have 8-10 weeks to train prior to a mission. If time is limited, a platoon may train three times per week if adequate time for recovery is allowed.

Heavy strength and plyometric training on the same body area should not be performed on the same day.

However, upper body strength training may be combined with lower body plyometrics and vice versa. Adequate time for recovery from each type of training is needed and can take from 1-3 days, depending on the intensity. If schedules are tight, the intensity of strength and plyometric exercises should vary from low to high to allow sufficient time for recovery. For instance, when high-intensity plyometrics is required (e.g., just prior to an operation) strength training should be of a lower intensity.

Plyometric Exercises

When performing jumps it often helps to think of “hanging in the air” for as long as possible, keeping shoulders parallel to the ground at all times. Emphasis should be on speed without sacrificing proper technique. Table 9-3 and Table 9-4 present a variety of plyometric exercises. Exercises are listed in increasing order of difficulty for each grouping in Table 9-3.

Table 9-3. Plyometric Exercises

Exercise	Intensity/ Direction	Description
Jumps in Place and Standing Jumps		
Squat Jump	Low/Vertical	Start in squat position and explosively jump upward to maximum height. Land in squat position and immediately repeat jump until all repetitions are complete. Keep hands behind head during entire movement.
Split Squat Jump	Low/Vertical	Start in lunge position. Explosively jump off front leg using calves of back leg to propel body upward. Maintain same position when landing and immediately repeat jump until all repetitions are complete. Perform exercise with other leg forward. Keep arms at sides during entire movement.
Cycled Split Squat Jump	Low/Vertical	Start in lunge position. Explosively jump off front leg using calves of back leg to propel body upward. While in midair, switch legs so back leg is in front during landing. Land in lunge position and immediately repeat jump switching legs each time. Keep arms at sides during entire movement.
Single Leg Tuck	High/Vertical	Stand on one leg, arms slightly behind body. Using arms and leg propel body upward as high as possible. While in midair, bring knee of jumping leg toward chest and quickly grasp knee with hands and release. Land and repeat jump until all repetitions are complete. No extra jumps between repetitions are allowed.
Double Leg Tuck Jump (Cannonballs)	Medium/ Vertical	Performed same as Pike Jump, but knees are brought toward chest while in midair and knees are quickly grasped with arms. Upon landing, repeat jump until all repetitions are complete.
Double Leg Vertical Power Jump (Toyotas)	High/Vertical	Start in squat position, arms slightly behind body. Using arms and legs, explosively jump as high as possible while reaching upward. Land and repeat immediately; repeat jump until all repetitions are complete. No extra jumps in between repetitions are allowed.

Table 9-3. Plyometric Exercises

Exercise	Intensity/ Direction	Description
Single Leg Vertical Power Jump (Michael Jordans)	High/Vertical	Stand on one leg, arms slightly behind body. Using arms and legs, propel body upward as high as possible while reaching upward with one or both arms. Land on one leg and immediately repeat jump until all exercises are completed. Perform exercise on other leg. No extra jumps in between repetitions are allowed.
Standing Triple Jump	Medium/ Horizontal with a Vertical Component	Start with legs shoulder-width apart, arms slightly behind body. Using legs and arms to propel body, jump upward and as far forward as possible. Land on right foot, and immediately jump off right foot and land on left foot. Immediately jump off left foot and land on both feet. When performing next set, land on left foot first, switching to right and then both feet. Repeat until all repetitions are completed. Try to travel as far as possible between each jump.

Multiple Jumps and Hops

Double Leg Hop (Bunny Hops)	Medium/ Horizontal with a Vertical Component	Start with feet shoulder-width apart, arms at sides. Jump up and as far forward as possible. Bring feet toward buttocks while in midair. Land and repeat jump until all repetitions are completed. Goal: to achieve maximum distance.
Front Hurdle Hop	Medium/ Horizontal with a Vertical Component	Begin with low obstacles, gradually increasing height with improvements in performance. Place 5 obstacles in a line approximately 1 meter apart. From a standing position, use both feet to jump over hurdles as quickly as possible, landing on both feet.
Single Leg Hop (Monte Pythons)	High/ Horizontal with a Vertical Component	Place one foot ahead of the other, as if taking a step. Rock onto front leg and push off (e.g., right foot). Bring knee of push-off leg up and as high as possible. Non-jumping leg is held in a flexed position throughout. Land on right foot, and immediately repeat exercise until all repetitions using one leg are completed. Repeat exercise using other leg to push off.

Table 9-3. Plyometric Exercises

Exercise	Intensity/ Direction	Description
Double Leg Speed Hop	High/ Horizontal	Stand with feet together, arms at sides and slightly extended behind body. Jump up and out as far as possible while bringing feet toward buttocks. Land in starting position, and immediately repeat jump until all repetitions are completed. Feet should be kept together throughout. Concentrate on speed, then distance, and last on height.
Single Leg Speed Hop	High/ Horizontal	Begin with 1 foot ahead of other. Rock onto front leg and push off (e.g., right foot). Bring knee of push-off leg up and as high as possible while in midair. Non-jumping leg is held flexed throughout. Land on right foot, and immediately repeat exercise until all repetitions using one leg are completed. Repeat using other leg to push off. Concentrate on speed, distance, and last on height.
Side Hurdle Hops	Medium/ Lateral	Place an obstacle on ground: height can be increased as performance improves. From standing position on both feet, jump sideways over hurdle, landing on both feet. Immediately jump sideways back over hurdle to starting position. Try to increase number of jumps performed within 30 sec.
Four Line Hop Drill	Medium/ Horizontal, Lateral, Diagonal	Draw a 5-ft. square on a flat surface. Start at point A facing out from square. Jump to point B, then C, then D and back to starting position. Perform as many jumps as possible in 30 sec. Develops speed and coordination in several directions: good drill for CQB training.
Double Leg Zigzag Hop (Ski Moguls)	Medium/ Diagonal	Set up course using about 10 cones, bags, or bodies 45-60 cm apart in a zigzag pattern. Start with feet shoulder-width apart, arms slightly behind body. Using arms and legs to propel body, jump diagonally over obstacles in place. Repeat until course is completed. Keep shoulders perpendicular to ground at all times.

Table 9-3. Plyometric Exercises

Exercise	Intensity/ Direction	Description
Bounds		
Alternate Leg Bound	Medium/ Horizontal with a Vertical Component	Begin with one foot ahead of the other. Rock onto front leg and push-off. Bring knee of push off leg up and as high as possible while in midair. Think of hanging in air to increase distance traveled. Prepare legs and arms for landing. Land on opposite leg and immediately repeat bound, alternating legs with each bound until all repetitions are completed. Goal: to cover as much distance as possible.
Combination Bound	Medium/ Horizontal with a Vertical Component	Begin with 1 foot ahead of the other, as if taking a step. Rock onto front leg and push off (e.g., right foot). Bring knee of push-off leg up and as high as possible while in midair. Land on right foot, and immediately explode off right foot and land on right foot again. Immediately explode off right foot and land on left foot. After landing on left foot, immediately jump off left foot and then land on right foot. Foot sequence is right-right-left. Repeat sequence until all repetitions using 1 foot are completed. Repeat using opposite leg.
In-Depth Jumps	Shock/ Vertical or Horizontal	Start on heels of both feet, toes slightly hanging over side of box, arms to sides and slightly back. Step off box (do not jump) and land on balls of feet, almost shoulder-width apart, knees flexed. Propel body upward immediately (if vertical height is goal) or forward (if horizontal distance is goal) using arms and legs to propel body in desired direction.
In-Depth Jumps/Box Drills		
Box Jumps (Single or Double Leg)	Shock/ Vertical or Horizontal	Place 4-8 boxes 1 to 2 m (3 to 6.5 ft.) evenly apart, depending on amount of horizontal movement desired; 1 box also may be used. Foot contact may be on 1 or both feet, but 1-leg lands are highly intense and should only be done by those doing advanced plyometrics and a body weight less than 100 kg (220 lbs.). Start about 0.6 m in front of first box, feet shoulder-width apart and slightly flexed, arms to sides and slightly back. Jump forward and up off both legs to land on first box. Foot contact may be double or single. Upon landing immediately explode off the box and onto ground. Upon landing on ground, immediately explode off ground and as high or forward as possible (if using one box) onto next box.

Table 9-4. Upper Body Plyometrics

Exercise	Intensity	Description
Forward Ab Throw	Low	Kneel on floor holding a medicine ball behind head with both arms. Use abdominals to throw it forward. Motion requires a bend at waist and follow through with arms.
Medicine Ball Sit-Up	Low	Starting position for lead partner is sitting on the deck, legs on the deck, shoulder-width apart and flexed at a 90° angle. Support partner stands 1.5 to 2 m (5 to 6.5 ft.) in front of lead partner holding medicine ball. Support partner passes medicine ball to lead partner at chest level. Lead partner catches medicine ball and allows the weight of the ball to push the upper body back and down. When the lower back touches the floor (do not wait till the shoulders touch), lead partner immediately sits up and performs a chest pass to support partner.
Medicine Ball Chest Toss	Low	This exercise may be performed using a partner or a wall and a medicine ball that rebounds. Holding medicine ball at chest level, throw ball forward with a pushing motion. Keep arms slightly extended following release. After ball rebounds off wall or your partner returns it, catch ball with arms extended, swing the weight and momentum of ball as resistance against flexing arms. Repeat throw.
Drop Push-Up	Shock	Starting position is kneeling on deck with torso perpendicular to deck. Keeping torso straight, lean forward, catching body with hands. Hands should be wider than shoulder-width apart and flexed.
Side Ab Throw	Low	This exercise may be performed using a partner or a wall and a medicine ball that rebounds. Stand with one side of the body toward the wall or partner holding the medicine ball on the opposite side. With a sideways motion at waist level, throw the ball across the body toward your partner or wall. The torque should come from the waist. Stay in this position to catch the ball when it is returned and swing back in starting position to repeat throw.
Plyometric Sit-Up	Low	Lead partner lies with back on deck, legs perpendicular to floor. Support partner stands with 1 foot on each side of lead partner's head while grasping his legs at ankle. Lead partner grabs ankles of support partner. Support partner pushes legs of lead partner forward and toward deck. Lead partner provides slight resistance to force while allowing legs to accelerate toward deck. Before legs touch ground, lead partner quickly lifts them back to starting position.

Table 9-4. Upper Body Plyometrics

Exercise	Intensity	Description
Medicine Ball Push-Up	Medium	Start in push-up position with hands supported by medicine ball. Quickly move hands off medicine ball and drop toward deck. Catch weight of body as it drops with arms slightly wider than shoulder-width apart and flexed. Chest should almost touch medicine ball. Rapidly extend arms to propel body upward. At maximal height, arms should be placed on medicine ball as in starting position. Catch weight of body and immediately repeat exercise.
Push-up with a Clap	High	Starting position is same for push-up. Flex arms, bringing body toward deck as if performing a push-up. Using arms to propel body upward, immediately push body off deck in time for hands to clap prior to landing in starting position. Repeat exercise.

Eccentric Downhill Training

Many SEAL missions (e.g. small unit patrolling) involve overland movement. Mountain and/or downhill hiking can result in severe muscle soreness, injury to muscle tissue, and strength loss that can last for several days, if you are not accustomed to such activities. A recent Naval Health Research Center study found that as few as two downhill training runs (e.g., treadmill or mountainous terrain) one week apart could greatly minimize the muscle soreness and damage. This method of conditioning leg muscles is an effective way to prepare SEALs for future missions or events involving rugged terrain. Uphill and downhill training hikes with loads are also an effective means for conditioning legs.

Chapter 10

Load-Bearing

Extended humping with a load is one of the most physically demanding tasks for a SEAL. As a SEAL, you must carry loads into rivers, jungles, deserts, and mountains as well as arctic areas and be prepared to engage in various styles of fighting and methods of infiltration. In the planning phase of these missions, Navy SEAL platoon leaders are frequently faced with decisions as to what type and how much equipment and ammunition to carry on a mission: common (minimum) and critical (mission specific) equipment need to be chosen wisely.

The development of multiple weapon systems and state of the art surveillance equipment has increased the firepower and protection of the individual warrior. However, the same equipment that is designed to provide a technological advantage in battle may also provide a load-bearing challenge.

Much remains to be learned about carrying heavy loads for both short and long distances. Moreover, weather, terrain, water discipline, acclimation status and other factors that impact load requirements must all be considered.

Both excessive fatigue and muscle strain during long humps can usually be explained by inadequate training for the unique physical demands of this task.

To assist you in maintaining readiness for tasks that involve carrying heavy loads, the following information is presented:

- ◆ Physiological and environmental factors.
- ◆ Optimizing load-bearing.
- ◆ Physical training for load-bearing.
- ◆ Common medical conditions.

Physiological and Environmental Factors

Body and Load Weight

Ideally, it is best to select the load-bearing weight as a function of body weight rather than selecting an absolute load-weight per man. You may not have the flexibility to tailor the load weight per man due to mission requirements. Therefore, an upper weight limit for load-bearing should be calculated so the load will not create a higher physical demand (energy cost) for individuals with smaller stature and lower lean body weight.

Determining the maximum weight of the load is a more important factor affecting load-bearing than the type of load carriage design. Numerous studies have examined the optimal load-bearing weight you should maximally carry before there is a disproportional increase in the rate of energy expenditure. This is calculated as a percentage of body weight. Although those who are physically fit according to Physical Fitness Test Scores can typically carry 45% of their body weight for 8 hours at a pace of 4 mph, a lighter load is considered optimal.

“Rule of Thumb”: A maximal load should be 40% of body weight. Example: 40% of 170 lbs. is 68 lbs.

The energy cost of the task rises steeply beyond this percentage. It has been reported that the energy cost of humping with a load increases proportionally with the weight carried. For loads more than 40% of body weight, the energy expenditure rises disproportionately and fatigue occurs sooner. **The key is to carry your load as close as possible to your body’s center of gravity.** This will result in the lowest energy cost when you carry a load, which is evenly distributed, on your back.

Biomechanics of Load-Bearing

The duration of time your foot is on the ground during a normal gait does not increase until pack loads are greater than 50% of your body weight. However, the length of time your foot is in the air during the swing phase of your gait decreases with increasing load-bearing weight. This response occurs to increase the length of time both feet are on the ground for double support. As the load weight increases, your feet increase the ground force downward, forward, rearward and in lateral directions. Shorter stride lengths will increase stride frequency and help maintain normal walking patterns during moderate to heavy load-bearing.

Shorter strides may minimize strain and possibly reduce lower back and lower extremity injuries.

Load-Bearing and Walking Pace

Self-pacing during load-bearing results in a lower energy cost than a forced-pace. However, not all missions allow self-pacing. When the pace is forced, a self-selected decrease in walking pace will be observed as the load-bearing weight increases. The self-selected walking pace or exercise intensity during load-bearing depends on many factors. Some of the factors affecting the self-selected pace include:

- ◆ Load weight
- ◆ Aerobic fitness level (maximal aerobic capacity)
- ◆ Total distance walked

You will normally self-pace at 30% - 35% of your maximal aerobic capacity when carrying a moderate load of 50 pounds.

With lighter loads, self-pacing normally results in an exercise intensity of around 45% of your maximal aerobic capacity. However, an exercise intensity of 60% or greater can be achieved when the load is light and the distance short. **Remember: walking pace and load weight carried during an infiltration or exfiltration contribute to the rate of exhaustion.** Figure 10-1 presents estimates of when exhaustion might occur at various walking speeds and loads. High rates of energy expenditure (900 to 1000 calories per hour) can be sustained for only 6 to 10 minutes. To be able to move quickly at this intensity, load weight must be light.

Figure 10-1. Workload and Energy Expenditure During Load-Bearing

Carrying a load at a walking pace that requires an energy expenditure in excess of 300 kcal per hour can compromise the energy reserves you will need at the desired destination. Figure 10-2 shows the speeds that you can expect to sustain with given loads at the designated paces: note these all result in an energy expenditure of 300 kcal per hour.

Figure 10-2. Effects of Walking Pace by Pack Weight and Terrain

Hydration Status

Appropriate water/fluid discipline must be observed at all times during load-bearing. Exercise without a load is severely compromised when dehydration occurs, and **when exercise is coupled to load-bearing, dehydration potentially becomes an even greater threat.** This is true regardless of the environmental conditions. *The Navy SEAL Nutrition Guide* provides information on optimal fluid ingestion, but in brief, **you should ingest at least one to two cups of fluid every 30 minutes during a hump.**

Fluid requirements are higher during exercise with load-bearing than during exercise without load-bearing.

Environmental Stress

- ◆ **Hot and dry or hot and humid environments** will increase the heat strain of individuals during load-bearing. Thermal heat load will be increased due to body heat production from load-bearing activities, and from the heat load from the sun and other heat sources in the environment. ALICE packs and double packs can restrict the body's ability to dissipate heat. Load-bearing vests with a nylon mesh body will trap less heat than backpack designs.
- ◆ **Cold environments** increase the energy cost of walking because the clothing worn is usually heavy and cumbersome. This can result in overheating and sweating, especially on the back where the load is carried. Hypothermia (drop in body temperature below 95°C) can also occur rapidly in cold environments if the inner layers of clothing are wet when you stop exercising.
- ◆ **Moderate to high altitudes** decrease exercise capacity since the available oxygen in blood decreases as altitude increases due to lower barometric pressure.
- ◆ **Sandy terrain** significantly increases energy expenditure up to 80% or greater as compared to walking on a firm surface. The energy demand increases with the difficulty of the terrain.

Sleep Loss

Lack of sleep can compromise your mental capacities, including attention, logical reasoning, and mental processing. In contrast, physically demanding skills seem little affected by up to 72 to 96 hours of sleep loss.

Protective Clothing

The type of clothing worn during load-bearing is an important consideration for dissipation of body heat. Mission Oriented Personnel Protection (MOPP) gear for nuclear, biological and chemical environments (NBC) is a very heat-restrictive garment.

Guidelines with estimates for work/rest cycles and hydration guidelines when in MOPP gear are available. With load-bearing activities in MOPP gear, work/rest guidelines should be adjusted downward and hydration requirements adjusted upward, since load-bearing activities have not been accounted for. The use of MOPP gear will be equivalent to adding 10° Wet, Bulb, Globe, Temperature (WBGT) to the existing ambient temperature. Therefore, the medical threat of heat illness will increase substantially in MOPP clothing.

Physical Training for Load-Bearing

Most regular home exercise programs and weekly NSW training programs are not adequate for the physical demands of moderate to heavy load-bearing. This section is designed to provide you with an appreciation of the physical demands of load-bearing and an approach to initiating load training.

Elements of a Load-Bearing Conditioning Program

The key elements for conditioning for load-bearing incorporate strength, speed and endurance training while relying on the principle of specificity of training (see Chapter 1: Overview of Physical Fitness). These are as follows:

- ◆ **Load-bearing progressive marches:** Specificity of training is one of the basic training principles. To become better or more skilled at a particular event, the event must be practiced. To be able to carry heavier loads for longer periods of time, loads must be carried in training.
- ◆ **Resistance strength training:** Load-bearing requires strength. Strength training will help improve load-bearing ability and performance.

- ◆ **Aerobic training:** Aerobic capacity is very important with respect to load-bearing. Individuals with the highest maximal oxygen consumption are better able to tolerate the physical demand of moderate to heavy load-bearing and walk at a faster pace for longer durations with less fatigue than individuals with a lower aerobic capacity.
- ◆ **Anaerobic training:** Anaerobic power and muscular strength are needed for high intensity combat activities. Different muscle groups are used depending on the type of load-bearing tasks, whether it is a fast paced, short hump or a slower paced, long hump.

Strength training or endurance running alone will not improve load-bearing ability.

The best training for load-bearing is cross country marches with a pack.

Initiating Load Training

Basic guidelines should be followed when beginning heavy load-bearing training.

- ◆ Start with loads 20% of your body weight and short distances (5 miles) once per week at the beginning.
- ◆ Progressively increase pack weight for each training session after two weeks: Loads should be increased to 25%, 30%, and 40% of body weight or greater (depending on the mission requirements).
- ◆ After achieving pack weight of 40% of weight, progressively increase distance: 7.5, 8, 9, 10, to at least 12.5 miles. Maintain distance for at least one month.

Maintaining Load-Bearing Fitness

To maintain fitness for humping a load equivalent to 40% of body weight for 10 miles would require at least:

- ◆ Upper and lower body weight training two days per week.
- ◆ Running three to four days per week for 30 minutes per session.

- ◆ One hump at least every other week, preferably once per week.

Optimizing Load-Bearing

The decision to calculate an optimal load-bearing weight per man is a difficult task. It is challenging to define an optimal load, since no “hump” is going to be conducted under ideal conditions. Factors such as walking pace, weight carried, climate, grade, type of terrain and clothing, etc., will all vary on any particular mission. Table 10-1 presents factors essential for ensuring energy conservation and comfort. These factors combined with proper physical training, will serve to optimize your load-bearing.

Table 10-1. Optimizing Load Carriage

Loads should be close to the center of the body.

Distribute the volume and weight of the load proportionately on the front and back of the chest.

Chest movement should not be restricted by the load-bearing vest or rucksack.

Adjust the pack so that overloading or straining of muscles is avoided.

Maintain normal posture and walking patterns.

A large padded waistbelt spreads 80% to 90% of the weight over the pelvic girdle.

Increase comfort by transferring most of the pack’s weight to the waist belt by the use of a flexible frame.

Common Medical Conditions

A number of acute medical conditions are associated with load-bearing. Most are minor, but any one can potentially affect your ability to maneuver quickly and ultimately slow down the walking pace of the squad or platoon. By understanding the range of medical problems, you will be able to better prevent, assess and treat these injuries. These medical conditions are all covered in Chapter 12: Training and Sports Related Injuries. The most common injuries incurred during load-bearing are:

- ◆ Foot blisters (See Appendix C).
- ◆ Back pain.
- ◆ Stress fractures.
- ◆ Rucksack palsy.
- ◆ Dehydration.
- ◆ Other minor lower extremity injuries, such as foot and knee pain.

Conclusion

Appropriate aerobic and anaerobic training, along with bi-monthly training humps, will improve your ability for load-bearing, lower energy demands, and reduce the frequency of musculoskeletal injuries.

Chapter 11

Training for Specific Environments

Physical training in extreme conditions, such as hot, cold, or high altitude environments, presents special challenges. Even highly accomplished athletes can be quickly overcome by “environmental exposure” injuries if proper preparation is overlooked or if signs and symptoms of impending illness are ignored. To compound matters, many extreme environments tend to be isolated and difficult to access. Proper planning and preparation before entering such areas can help ensure safe and beneficial training.

One way of adapting to a new environment is **“acclimation”**. Acclimation is defined as *the continuous or repeated exposure to heat, cold, altitude, or some new environment so as to provoke physiologic or biochemical changes that allow you to better tolerate the new environment*. Thus, acclimation is the gradual change the body goes through as it adapts to a new environment. This chapter will focus on training under environmental conditions which require acclimation, and also under confined spaces.

Training in Hot Environments

Exercising in hot, humid environment imposes a significant challenge on the body. The human body maintains tight control of body temperature through several different mechanisms. Under conditions which impose large heat loads (example: strenuous exercise or wearing protective gear in a hot environment), the primary mechanism for cooling is evaporation of sweat from the skin or evaporative cooling. Relative humidity is the most important factor governing evaporative cooling: when the humidity is high, evaporation is greatly limited.

Your skin is like the radiator of a car; as the temperature of the body core rises it warms the blood and pumps it to the skin to cool off. Sweat is released at the skin and absorbs the heat from the warmed blood. As sweat is warmed, it is vaporized the same way boiling water turns to steam and thus removes a large amount of heat from the body. Only sweat that evaporates can effectively cool the body; sweat that “drips” is essentially wasted fluid and provides little or no cooling effect. The body maximizes evaporative cooling by:

- ◆ **Increasing Heart Rate:** An increase in the heart rate increases blood flow to the skin and results in greater heat transfer to sweat and vapor.
- ◆ **Increasing Sweat Volume:** Beginning to sweat earlier and recruiting more sweat glands increases the rate of sweat production, therefore cooling.

How hot is too hot? The degree of danger posed by a hot environment is usually determined by the wet bulb-globe temperature (WB-GT). If the WB-GT is over 87° F (30.5° C) or if no WB-GT is available and the temperature is over 85° F with a relative humidity of 60% or above, exercise should be avoided or undertaken with caution.

Factors that Hinder Body Cooling in the Heat

- ◆ **Humid Heat:** As the humidity increases, evaporative cooling slows due to saturation of the air with moisture.
- ◆ **Skin Disorders:** Injuries such as deep thermal burns, sunburn or rashes will prevent or hinder sweating.
- ◆ **Clothing:** Any clothing that is impermeable to water vapor will compromise cooling.

Heat Acclimation

Adapting to a hot environment can take one to three weeks; for physically fit individuals, 75% of acclimation occurs during the first week of heat exposure. During this time, sustained physical activity is more difficult and onset of fatigue occurs with minimal physical exertion. Acclimation involves two parts:

- ◆ **Cardiovascular adaptations:** Changes that gradually lead to a lower heart rate for a given workload or intensity of exercise. This is the most rapid change during acclimation to heat.
- ◆ **Sweating:** Sweating begins earlier with exertion; sweat rate is higher and can be sustained for longer periods of time. Sweat also becomes more dilute thus saving essential body electrolytes.

Maximizing Acclimation

Maintain Aerobic Fitness

A solid base of endurance training established before you enter a hot environment will ease the cardiovascular strain encountered during acclimation. Pre-acclimation endurance training must be rigorous enough to raise core temperatures for acclimation to be most beneficial. Aerobically fit individuals will retain heat acclimation longer once removed from a hot environment than less fit personnel. **Remember:** Aerobic fitness will help speed the acclimation process but is not a substitute for it.

Exercise in a Hot Environment

Any form of physical exercise will hasten acclimation. However, the intensity will be lower than what you are used to. Refer to your local medical officer for guidance. If the environmental conditions permit, gradually increase the intensity of exercise until you reach the desired workload or level of training.

Maintain Adequate Hydration

Acclimation results in an earlier onset of sweating as well as an increase in the sweating rate. These changes translate to an increased need for fluids. Acclimated personnel may produce as much as 8 to 10 liters (8.5 to 10.5 quarts) of sweat per day. Thirst cannot be used as a “measuring stick” for proper hydration. When training in hot environments, a minimum of 10 to 12 quarts of water per day should be consumed, but not more than 5 cups per hour. Drinking at frequent intervals will decrease the risk of a potentially fatal heat stroke.

Maintaining Acclimation

Heat acclimation cannot be maintained unless there is repeated heat exposure and even if repeated exposure is maintained, other factors may cause a loss of acclimation. Factors that lead to loss of heat acclimation include:

- ◆ Sleep loss.
- ◆ Alcohol.

- ◆ Dehydration.
- ◆ Salt depletion.
- ◆ Illness/Infections.
- ◆ Cessation of physical activity.

There is some disagreement as to how long it takes to lose acclimation to heat, but generally speaking after 2 weeks of working in a hot environment, it will take 3 to 4 weeks before most of the adaptations are lost.

Heat Injuries

There are many categories and subcategories of heat injuries. However, there are three classes of heat-induced injuries that will be considered here:

- ◆ **Heat cramps** are painful contractions of muscles (usually in the extremities) following vigorous exercise. They occur most commonly in unacclimated personnel. No specific cause is known (possibly depletion of electrolytes), but such cramps usually resolve when acclimation is complete.
- ◆ **Heat exhaustion** is a potentially serious injury resulting primarily from dehydration and electrolyte depletion. The affected individual may feel light-headed, dizzy, nauseous, fatigued, or develop a headache. If heat exhaustion is suspected, the injured individual should be placed in a cool location if possible and given replacement fluids by mouth or intravenously.
- ◆ **Heat stroke** is a **life threatening** injury in which the affected individual loses the ability to regulate temperature and is overcome by soaring body core temperatures (greater than 104° F). Such high temperatures can irreversibly injure vital organs and result in death if not rapidly treated. Many factors may contribute to heat stroke -- even well hydrated personnel may become victims if they ignore the warning signs and symptoms (see the following Table).

Table 11-1. Warning Signs of Heat Stroke

Signs to Be Aware of	
Light-headedness	Headache

Table 11-1. Warning Signs of Heat Stroke

Signs to Be Aware of	
Confusion	Nausea/vomiting
Loss Of Consciousness	Combativeness

Immediate medical attention is necessary to prevent death. Always remember the basics of first aid and check the ABC's first (Airway, Breathing and Circulation). If possible, move the injured person to a cool area and remove all of the person's clothing. Wet the body with a fine mist of water or pour cool water over the body and fan to facilitate cooling. If ice is available, apply bags of ice to the arm pits, groin and sides of the neck. Medical personnel should start intravenous fluids and oxygen if possible and transport the individual to the nearest medical treatment facility.

Many drugs and chemicals can decrease your ability to tolerate the heat, and knowing which ones may interfere with performance can be important on missions in hot environments. Table 11-2 presents some of the most common drugs that should be avoided in hot weather.

Table 11-2. Drugs and Chemicals to be Avoided in Hot Environments

Caffeine	Alcohol	Decongestants
Atropine and other anticholinergics		Antihistamines

Summary for Hot Environments

- ◆ Prepare by maximizing aerobic fitness -- this will greatly help in sudden in-out ops where gradual acclimation is not possible.
- ◆ Plan work-out to avoid heat of the day.

- ◆ Optimize acclimation by a carefully scripted exercise program from the medical department.
- ◆ Plan for decreased physical performance the first two weeks.
- ◆ Maintain proper hydration.
- ◆ Be aware of any illness that may predispose to dehydration (diarrhea, vomiting, fever).
- ◆ Always be aware of the warning signs of heat illness: Pay attention to your body. Slow down or stop if signs or symptoms of heat injury become apparent.
- ◆ Avoid drugs and other substances that predispose to dehydration or heat injuries.

Training in Cold Environments

Cold climates represent the harshest environments and pose the greatest threat to survive that SEALs face. An unprotected man in an extremely cold environment will perish much faster than when exposed to extreme heat. In cold weather, the human body attempts to maintain a warm core temperature primarily by physiologic mechanisms and behavioral adaptations:

- ◆ **Increased Metabolic Heat Production:** This occurs as the body's fuels (carbohydrates, fats and proteins) are metabolized or “burned” at the cellular level. Shivering represents involuntary muscle contractions that can increase the body's metabolic rate five to six times above normal.
- ◆ **Peripheral Vasoconstriction:** Blood vessels near the surface of the skin constrict or narrow in an effort to divert warm blood away from the cool surface of the skin.
- ◆ **Behavioral Adaptations:** Mans greatest asset in cold weather is his ability to create a warm micro-environment by wearing appropriate protective clothing or seeking shelter. He can also increase resting metabolic heat production by 10 times through vigorous exercise.

What is a cold environment? As with a hot environment, the temperature alone is not necessarily the best indication of coldness. In the heat, humidity, and in the cold, the wind, can greatly change your comfort level. In the cold, wind accelerates heat loss by replacing the warm layer of air surrounding the body with colder air. As a rule, you can be

sure it is a cold environment when the ambient temperature is below 15° F and the wind speed is greater than 25 mph. Such environments pose potential dangers to those exposed for any length of time.

Factors that Compromise Adaptations to Cold

- ◆ **Inadequate Energy Intake:** Reduces the ability to generate “metabolic” heat.
- ◆ **Injury or Poor Physical Conditioning:** Inhibits ability to generate heat through vigorous exercise.
- ◆ **Dehydration:** Places greater demands on the heart and speeds up fatigue.
- ◆ **Low Percentage of Body Fat:** Subcutaneous fat has insulating properties which help protect against heat loss. This is a concern for SEALs, who usually have low body fat.
- ◆ **Excessive Sweating:** Dress appropriately using a layering system and ventilate as necessary to avoid excessive sweating. Sweat will destroy the insulating qualities of cold weather clothing and cause unwanted cooling by evaporation and freezing.
- ◆ **Alcohol:** Increases peripheral blood flow which promotes heat loss and causes core temperature to fall more rapidly.

Acclimation to the Cold

Unlike acclimation to hot environments, there is little evidence to suggest that in humans, there is a significant physiologic adaptation to the cold. There is evidence to suggest that hands which are exposed to the cold for 30 minutes per day for three weeks will receive more blood flow and gradually become more “functional”. However, there is greater heat loss through hands conditioned in this manner.

Cold Injuries

The spectrum of cold injuries experienced in the SEAL community is broad, but all can be avoided by wearing appropriate clothing and paying attention for signs and symptoms of cold injuries.

Hypothermia

A lowering of body core temperature below 95° F is not an uncommon cold injury of SEALs and mild hypothermia is a relatively easy injury to treat. Moderate to severe hypothermia is less common and should be treated as a medical emergency. Some warning signs of a falling body core temperature include:

- ◆ Uncontrollable shivering.
- ◆ Slurred speech.
- ◆ Clumsiness.
- ◆ Slowed thought process.
- ◆ If shivering stops but all other signs are present - it could be an indication of severe hypothermia.

If any of the above signs occur, **immediate action** should be taken to prevent further injury or death. Always handle personnel suspected of having hypothermia gently - do not allow them to perform vigorous exercise to warm up as this may cause cardiac arrest. Remove wet clothing and place the individual in dry blankets or sleeping bag with one or two other dry and warm personnel. **Never completely immerse a hypothermia patient in warm/hot water as this may result in cardiac arrest.** Passive rewarming is usually satisfactory for mild hypothermia, but may not be adequate for severe cases.

Gentle rewarming is the safest method of restoring normal body temperature.

Frostbite

Frostbite is a freezing injury which most commonly affects the hands and feet. However, it can occur to any surface of the body that is not adequately protected. Symptoms often follow a progressive pattern to include the initial sensation of cold followed by numbness and eventually pain during rewarming. The skin may appear normal or appear pale. **If a frostbite injury is suspected, attempts to thaw the affected tissue should be avoided until there is absolutely no chance of it refreezing.** Frostbitten feet should not be thawed if it is necessary for the injured to walk unassisted to the extraction or medevac site. Rewarming is associated with severe pain and may turn walking wounded casualties into nonambulatory casualties. All cases of frostbite require evaluation at a definitive medical treatment facility.

How to avoid freezing injuries

- ◆ Dress appropriately and keep hands and feet as dry as possible.
- ◆ Do not touch metal with bare hands/skin. Tape frequently touched metals to reduce this risk.
- ◆ Wear protective goggles when exposed to high wind speeds such as in snow-mobiles, aircraft, skiers.
- ◆ Use the “buddy system” to check each other for unprotected skin.

Immersion Foot

Also known as “trench foot”, this nonfreezing foot injury results in tissue and nerve damage after prolonged exposure of wet feet to the cold (32 to 50° F). Immersion foot can be prevented by keeping feet as dry as possible and by avoiding tight fitting boots.

Nutritional Requirements

Special attention should be paid to nutritional requirements in cold environments. Energy requirements may increase several fold because of the increased work associated with performing physical tasks in cold weather and the caloric losses to shivering which can rapidly deplete glycogen stores. Carbohydrates are an excellent source of energy for replenishing depleted glycogen. Refer to the *U.S. Navy SEAL Nutrition Guide* for specific nutritional needs during cold weather operations.

Summary for a Cold Environment

- ◆ Check weather conditions and dress appropriately.
- ◆ Allow for a longer warm up.
- ◆ Avoid profuse sweating.
- ◆ Replenish body fuel (carbohydrates) during endurance events.
- ◆ Maintain hydration.
- ◆ Avoid drugs that cause dehydration: alcohol, caffeine.
- ◆ Be aware of the signs of cold injury.
- ◆ Use gentle rewarming for hypothermia victims.

Training at Altitude

An athlete's performance can suffer dramatically when he rapidly ascends to altitude. Several factors contribute to this decrement in performance but the most significant factor is the relative hypoxia or lack of oxygen available to do work at higher altitudes. Many changes occur during extended exposure to high altitudes; most occur after 2 to 3 weeks. The major adaptations that affect performance and ability to do work include:

- ◆ Increased oxygen carrying capacity of the blood.
- ◆ Increased density of blood supply to and within muscle.
- ◆ Increased oxygen carrying capacity of muscle.
- ◆ Increased respiratory rate.

Decreased oxygen at altitude reduces the maximal aerobic capacity of an athlete by 1% to 2% for every 100 meter (328 feet) rise above 1,500 meters (4,918 feet). Therefore, an elite endurance athlete may only be able to perform at 65% to 85% of maximal aerobic capacity at 10,000 feet when compared to sea level. Athletes that compete in anaerobic events, such as sprinters or weight lifters who perform brief (2-3 minutes) episodes of maximal effort events, may notice no initial difference in performance because sustained maximal oxygenation of muscle tissue is not necessary.

Acute Mountain Sickness

Acute Mountain sickness or AMS is typically a transient mild illness resulting from ascents to altitudes above 8,000 feet (2,440 meters) or ascents at a rate greater than 1,000 feet (305 meters) per day above 8,000 feet. Symptoms include headache, nausea, vomiting, fatigue and poor appetite. The symptoms usually disappear within a few days. Some individuals, however, may have to descend to gain relief. Life threatening complications of AMS include High Altitude Pulmonary Edema (HAPE) and High Altitude Cerebral Edema (HACE); both require immediate descent. The incidence and severity of AMS may be reduced by taking Acetazolamide (Diamox) 24 to 48 hours prior to and during an ascent. The dosage is 125 mg. by mouth, twice a day for two days, but this medication should only be given under the direction of a physician.

When participating in high altitude operations, you should report any of the following symptoms to your corpsman or medical officer:

- ◆ Cough or progressive shortness of breath.
- ◆ Coughing up blood or frothy spit.

- ◆ Progressive symptoms of headache.
- ◆ Mental confusion or difficulty thinking.
- ◆ Visual disturbances.
- ◆ Lack of urination in excess of 8 hours.
- ◆ Excessive irregular breathing.

Other Factors that Hinder Performance at Altitude

Temperature

In general, temperature decreases 6.5° C for every 1,000 meter rise in elevation (or 11.7° F/ 3,280 ft.). At extreme altitudes (above 5,000 meters or 16,400 ft.), the combined effects of hypoxia and hypothermia may make sustained aerobic activity extremely difficult if not impossible.

Dry Air

Relative humidity falls as one ascends. Combined with the increased ventilatory rate experienced at altitude, significant water loss can occur from the normally moist respiratory passages. Cold temperatures will also cause an increase in urinary output and together these two sources of water loss can result in rapid dehydration. Thirst cannot be used as a “measuring stick” for hydration status and personnel must constantly replace fluids with frequent water breaks.

Weight Loss

Most people who ascend to 13,000 feet (4,000 meters) or higher will experience a weight loss of 3% to 5% in the first 2 weeks at altitude. Some of this loss is muscle mass and appears to result from a decrease in the size of individual muscle fibers. There are several reasons for this weight loss:

- ◆ Increased energy expenditure.
- ◆ Decreased appetite due to a direct effect of hypoxia and a decreased sense of taste.
- ◆ Loss of body water.
- ◆ Acute Mountain Sickness - Please refer to *The Navy SEAL Nutrition Guide* for dietary recommendations at altitude.

Acclimation to Altitude

Prolonged exposure to altitude will bring about several physiologic changes and result in improved exercise tolerance at submaximal effort levels. At levels above 10,000 feet (3,050 meters), maximal aerobic capacity is limited and is lower than what would be measured at sea level. Below 10,000 feet, maximal aerobic capacity may approach sea level values, but usually only after a 2 week acclimation period. Because of this inability to achieve maximal aerobic capacity above 10,000 feet, elite endurance athletes may experience mild to moderate aerobic deconditioning with extended stays at altitude.

Training in Confined Spaces

During deployments or extended training exercises it is not uncommon to be confronted with conditions which may limit physical training routines. Complete cessation of physical training will result in a significant and rapid reduction in both strength and endurance capacity (see section on Deconditioning). Submarines and small assault craft probably create the greatest challenge, but under almost all circumstances where time is not a limiting factor a reasonably well balanced training program can be maintained with a minimal amount of equipment. The following is a list of both aerobic and anaerobic training modalities for confined spaces:

- ◆ Calisthenics.
- ◆ Pull-ups and dips.
- ◆ Grip balls for grip strength.
- ◆ Resistance equipment such as the Exergenie which imitate swimming strokes and are very light weight.
- ◆ Therabands, another lightweight resistance tool to maintain strength in major muscle groups.
- ◆ Jump rope.
- ◆ Stair stepping (monotonous but good aerobic workout without need of special equipment).
- ◆ Plyoball.
- ◆ Free weights.
- ◆ Running in place.

For larger platforms or forward operating bases with physical security limitations, the following equipment in addition to weights should also be considered:

- ◆ Climbers
- ◆ Cycle ergometer
- ◆ Rowing machine
- ◆ Stair climber
- ◆ Treadmill
- ◆ Ski machine
- ◆ Upper arm ergometer

Physical fitness equipment on a submarine should, at a minimum, include a cycle ergometer, a rowing machine and free weights.

The stationary cycle and rowing machines should have a performance monitor to display time, distance, etc., so that progress on stationary equipment can be charted and monitored. Platoons deployed under confined circumstances can reduce the monotony of stationary equipment and boost training morale by creating competitions. Monitoring and charting each members daily PT progress will help demonstrate results, encourage physical training, and maintain physical fitness.

Deconditioning

When a person is unable to maintain his exercise program, for whatever reason, detraining or deconditioning occurs rapidly. Numerous studies have investigated the effect of detraining on cardiorespiratory fitness, and significant reductions in work capacity has been noted within two weeks. A 25% decrease in maximal oxygen uptake has been reported after three weeks, which is equivalent to a 1% decline in physiologic function for each day of inactivity. In addition, the proportion and size of the Type II fibers have been shown to decrease with detraining. In contrast, maximal muscle strength appears to be more resilient to periods of inactivity. **A reduction in maximal capacity only means that it will be harder for you to do a given task than prior to deconditioning.** You will still be able to do the work. Remember:

The benefits of training are

transient and reversible.

Although maximal aerobic capacity is not maintained without training, other key factors can lead to a decrease in aerobic capacity which will ultimately reduce your work capacity. These include:

- ◆ Increasing age.
- ◆ High altitude.
- ◆ Dehydration.
- ◆ Loss of lean body weight.

Chapter 12

Training and Sports Related Injuries

One of the hazards of being a SEAL or an athlete is becoming injured. In BUDS training, 1 out of 3 potential SEALs sustain an injury that may curtail training or require them to drop out of training. Sustaining either a sudden injury or an overuse musculoskeletal injury can mean loss of work days, forced rest, and pain for a period of days to weeks. More severe injuries result in scar tissue formation at the site of injury. Thus, the purpose of this chapter is to describe:

- ◆ Treatments for training-related injuries.
- ◆ Reconditioning for return to full activity.
- ◆ Types of training injuries.
- ◆ Common mission-related injuries.
- ◆ When to seek medical care.

The goal is NOT to have you treat your own injuries, but rather to be informed so that you will seek appropriate help when needed. Central to the rapid recovery from training-related injuries is a step-wise reconditioning program which starts immediately after the injury. Such programs are designed to arrest the inflammatory process, promote healing, and accelerate the return to full duty.

Treatments for Training-Related Injuries

Sudden, traumatic, or acute injuries to the musculoskeletal tissue quickly result in inflammation, a process characterized by localized warmth, swelling, redness and pain. If left unchecked, however, the inflammatory process rapidly leads to:

- ◆ Tissue congestion.
- ◆ Stiffness.
- ◆ Weakness.
- ◆ Decreased range of motion.
- ◆ Loss of normal function.

A highly successful Sports Medicine approach to accelerate the healing of any injury is to first decrease the inflammatory process (swelling, pain and warmth), and then increase the range of motion at the joint. **RICE** and **ISE** are the approaches used to achieve these goals.

RICE = Rest, Ice, Compression & Elevation

After decreasing inflammation by **RICE**, range of motion at the joint is achieved through continued use of ice (I), stretching of the injured ligament or tendon (S), and weight bearing exercises (E).

ISE = Ice, Stretching, & Exercise

Reduce Inflammation

RICE (rest, ice, compression, elevation) is appropriate for all strains and sprains. In general, if an operator cannot bear weight on the extremity, rest is indicated and x-rays to rule out a fracture should be completed as soon as practical.

- ◆ “**REST**” means applying no weight or only partial weight to the extremity; crutches should be used for locomotion. “Relative Rest” means decreasing activities that cause pain and replacing them with other activities that are pain-free.
- ◆ “**ICE**” means applying ice. This should continue until swelling has stabilized.

- ◆ **“COMPRESSION”** means applying an Ace wrap or similar compression wrap to the injured part for periods of 2-4 hours. **Never sleep with a compression wrap applied unless medically advised.**
- ◆ **“ELEVATION”** means placing the injured part above the level of the heart; this allows gravity to help reduce the swelling and fluid accumulation.

Application of Ice

Ice serves a variety of important roles in the treatment of training and sport injuries, including:

- ◆ Reduces swelling that accompanies inflammation.
- ◆ Decreases muscle spasm and pain.
- ◆ Allows for less painful range of motion.
- ◆ Enhances blood flow back to the site after it has been removed.

The operator should not wait for a medical evaluation before using ice.

All soft tissue or joint injuries, **except open wounds**, will benefit by **immediate application of ice** (See Table 12-1). Ice can be applied either passively or actively. Passive application is when you take some form of ice: crushed ice, ice slush, an ice pack, or snow and apply it to the injured body part. Active application is when you take the ice (perhaps in water frozen in a cup or bag) and massage the injured part with the ice. At home, a bag of frozen peas is an excellent way to passively ice the injured part, as the peas easily conform to the swollen area. After 20 minutes, the bag of peas can be tossed back into the freezer for reapplication later. The normal response to ice includes cold, burning, aching and finally numbness over the affected part. This progression occurs over 7-10 minutes.

**Ice can be applied either passively or actively.
Do not apply ice directly to the skin.**

Table 12-1. Tips for Applying Ice: Passive and Active

- **Apply ice to the area for 20 minutes as soon after the injury as possible.**
 - **Repeat this every hour the first day, then three times a day after the first day.**
 - **Use ice until swelling decreases: usually 2 - 3 days.**
-

Caution: To prevent skin or nerve damage, do not keep ice on for more than 20 minutes, especially when applying to the elbow, wrist, or behind/side of the knee.

Range of Motion

The term range of motion is used to describe the extent to which a particular joint can be moved; achieving complete range of motion is the goal, but sometimes injuries restrict the range of motion. During the 20 minute icing session, you should attempt to move the injured part through a pain-free range of motion. Days later you can attempt a resistance activity which stresses the injured part while moving the joint through a range of motion that can be tolerated. An example would be moving the ankle up and down against resistance applied by holding a towel under the foot (Figure 12-1). Continued elevation and use of a compression wrap while doing these exercises will retard swelling.

Figure 12-1. Moving the Ankle Through its Range of Motion (ROM) with Resistance

Non-Steroidal Anti-Inflammatory Drugs (NSAIDs)

All of you have taken non-steroidal anti-inflammatory drugs (NSAIDs) at some point in your career, either as prescribed by a physician or on your own. NSAIDs are often used as the first treatment for overuse injuries because they are effective: NSAIDs decrease the symptoms due to inflammation (i.e., swelling, pain, tenderness, fever associated with injury). Although they are usually available over-the-counter, they are not a medication to take lightly. NSAIDs are used in training related injuries when there is inflammation caused by:

- ◆ Tendonitis.
- ◆ Bursitis.
- ◆ Sprains/Strains.

In the case of an acute injury which involves bleeding (including bruising) or swelling, NSAIDs should not be started for 2 to 3 days or until the swelling has stabilized.

NSAIDs may cause side effects.

The most frequently reported side effects include:

- ◆ Gastrointestinal distress such as nausea, heartburn, or vomiting.
- ◆ Gastrointestinal ulcers/bleeding.

- ◆ Increased blood pressure.
- ◆ Decreased ability of blood to clot.
- ◆ Exacerbation of asthma.
- ◆ Potential kidney damage with long-term use.

Remember: NSAIDs should not be used, or should be used with extreme caution, in conjunction with alcohol, as both irritate the stomach. Table 12-2 provides a list of the most commonly prescribed (or over-the-counter) NSAIDs, with their generic and common brand name.

Table 12-2. Generic Names (and Common Names) for Various Non-Steroidal Anti-Inflammatory Agents

Generic Anti-Inflammatory Agents	
Aspirin (Bayer, Aspirin, Ecotrin)	Ketoprofen (Orudis)
Diclofenac (Voltaren)	Meclofenamate (Meclomen)
Diflunisal (Dolobid)	Nabumetone (Relafen)
Etodolac (Lodine)	Naproxen (Naprosyn, Anaprox)
Fenoprofen (Nalfon)	Oxaprozin (Daypro)
Flurbiprofen (Ansaid)	Piroxicam (Feldene, Antiflog)
Ibuprofen (Advil, Motrin)	Sulindac (Clinoril)
Indomethacin (Indocin, Indocin SR)	Tolmetin (Tolectin 200, Tolectin 600)

If you have stomach or other gastrointestinal tract problems, Tylenol (acetaminophen) may be a better choice for relieving muscle soreness than Ibuprofen- and Aspirin-based products.

Reconditioning for Return to Full Activity

After the pain and swelling are reduced and the desired range of motion is achieved, ask the physician, therapist or trainer to design a reconditioning exercise program with the overall goal of a **rapid return to full activity**. The exercises prescribed will be specific to the site and type of injury, and will work towards the following specific goals of maximizing:

- | | |
|---------------|-----------------------|
| ◆ Flexibility | ◆ Strength |
| ◆ Endurance | ◆ Power |
| ◆ Speed | ◆ Specific Duty Tasks |

Each step should be successfully completed in a step-wise manner before returning to unrestricted activity. Definitions of most of these terms can be found in Chapter 1, however, the importance of each is described next.

- ◆ Strength and flexibility are closely linked. If flexibility is not balanced around a joint, or strength is maintained through only part of the range of motion, the risk of delayed healing or re-injury is high.
- ◆ With respect to endurance, the muscle quickly becomes deconditioned during the body's repair process and fatigues. Endurance is important in an injured ankle for example, as it may feel strong when rested but be prone to re-injury as the muscles and tendons around it become fatigued with activity. The strategies for any rehabilitation program include improving individual muscle endurance while maintaining cardiovascular or total body endurance.
- ◆ In terms of power, a weak, deconditioned muscle is prone to re-injury when called upon to perform a power move. Strategies for developing power include rapid motion against resistance, use of rubber bands, medicine balls or weight machines.
- ◆ Sustained speed provides for reconditioning the injured part to anaerobic (without oxygen) activity and coordination of movement. Interval training (e.g., sets of 440 yards over 90 seconds) several times per week is an excellent supplement to the rehabilitation of a lower extremity injury, provided the operator performs the activity below the pain threshold.

Continued use of ice and intermittent application of electrical stimulation, ultrasound and other therapeutic modalities will help accelerate the rapid return to full activity.

Return to Mission-Related Tasks

Ultimately, the operator must return to performing **specific tasks required to complete the mission**. This component of reconditioning **MUST NOT** be overlooked. Determine the specific mission-related tasks or training that puts the operator at risk for re-injury. These tasks should be practiced at slower speeds in a controlled setting, and proficiency should be demonstrated prior to a return to full duty. The ultimate goal is to return the injured operator to controlled physical activity in 4-7 days for a mild to moderate injury and 1 to 2 weeks for a severe strain or sprain.

General Guidelines for Returning to Physical Activity

A number of general rules apply during the repair and reconditioning period. These include the following:

- ◆ If the operator has pain with flexibility work, vary the degrees of motion.
- ◆ If there is pain with strength and power work, vary the repetitions and/or weight.
- ◆ If there is pain with endurance or speed work, vary the distance and/or time.
- ◆ If there is pain with specific mission-related tasks, vary the quickness and/or time required to complete these tasks.

In summary, rehabilitation and reconditioning places its greatest emphasis on rapidly decreasing pain and increasing range of motion about the injured joint by using “**RICE**” and “**ISE**”, followed by specific exercises to maximize flexibility, strength, endurance, power, and speed, and using ice as necessary.

Types of Injuries

A variety of injuries can be encountered during SEAL and other forms of physical training. In this section we will start with those problems that may be relatively minor and cause mild discomfort, and then proceed to more serious injuries that may limit your activities.

Training-Related Muscle Soreness

Delayed soreness in a deconditioned muscle is normal, and is caused by micro-injury. Pain and tenderness typically appear 12 to 48 hours after beginning a training session. Stiffness and soreness are worse after the cool down and resolve again after warming up. This normal process usually persists for 7-12 days and then disappears.

Table 12-3. A Process of Alleviating Muscle Soreness

Ice
Stretch
Extended Warm-Up
Work-Out
Stretch
Ice

Contusions

A blow to the muscle belly, tendon or bony prominence may cause swelling and bleeding into the tissue and form a contusion. The blood may coagulate and eventually form scar tissue, impeding normal function. Passive ice therapy needs to be started as soon as possible. After swelling has stabilized, start with active icing and then use **Cross Friction Massage**. This is a simple technique used to reduce the swelling and congestion. The thumb or index and long fingers are used to apply firm pressure perpendicular to the long axis of the tendon or muscle (Figure 12-2). The injured part is rubbed in this manner for 10 minutes, four times a day.

Figure 12-2. Technique of Cross-Friction Massage

Sprains and Strains

Ligaments attach bone to adjacent bone and can be damaged in a fall, an accident, or through overuse. Such injuries are called sprains and include acute back sprains, knee sprains, or ankle sprains. Sprains are graded as mild, moderate or severe. Mild sprains refer to overstretching and microtears of the fibers. A partial tear, with or without instability or looseness, is considered moderate. A severe sprain implies a complete or near complete tear of tendon fibers that results in looseness or instability at the joint.

A sprain is a damaged ligament.

Tendons attach muscle to bone. Muscle or tendon injury is referred to as a strain or tendonitis. Tendonitis, including achilles tendonitis, shoulder tendonitis, hamstring or quadriceps muscle strains, fall into this category.

A strain or tendonitis is an injury to a muscle or tendon.

Mild to moderate lower extremity sprains and strains heal without residual problems if treated early. Primary treatment includes ice and NSAIDs, partial weight bearing with crutches as necessary, and early therapy to maintain range of motion at the joint.

Muscle Cramps

Muscle cramps are common and may be precipitated by prolonged physical activity, high heat and humidity (black flag conditions), dehydration and/or poor conditioning. Cramps are characterized by the sudden onset of moderately severe to incapacitating pain in the muscle belly and may progress to involve other adjacent muscle groups. The first treatment consists of immediate rehydration with a fluid containing electrolytes. After beginning rehydration, further treatment should consist of grasping and applying pressure to the muscle belly and immediately putting the muscle on stretch until the cramp resolves. The calf muscle, for example, would be stretched by flexing the foot toward the head, whereas a thigh cramp would be treated by flexing the knee, bringing the foot to the buttocks. Pictorial representations of procedures for treating these cramps are presented in Figure 12-3. In addition to these procedures, adequate rest should help prevent recurrences.

Figure 12-3. Examples for Treating Painful Muscle Cramps in the Calf and Quadricep Muscles

Fractures

A true fracture involves a break or chip in the hard outer surface of the bone. With few exceptions, true fractures of the lower extremity require a period of immobilization in a cast and supervised care by a medical officer.

Stress fractures differ from true fractures and are most commonly seen in the load-bearing bones of the lower extremities, i.e. pelvis, femur, tibia, fibula and bones of the foot. They are caused by excessive strain on the bone. Bone constantly undergoes remodelling and repair in response to the stress of weight bearing. The repair process is accelerated by rest, and is slowed in times of heavy exercise as with runs, hikes, marches and prolonged training. When the breakdown process exceeds the bone's ability to repair itself, a stress fracture may result. As the lower extremity bone becomes weakened, weight bearing activity, such as running, may cause a vague, achy pain at or near the weakened site. The first symptoms of stress fractures are initially poorly localized and often ignored. Later, as the process continues, the bone will become tender in a very localized area and will often ache at night or at rest. Ultimately, if left untreated, continued weight bearing may cause a true fracture within the weakened area of bone. Physical training factors which increase the risk for stress fractures include:

- ◆ A change in training surface (grass to asphalt, dirt to concrete).

- ◆ A change in shoe wear (worn out shoes or boots or new running shoes or new boots).
- ◆ An increase in physical activity (too much, too fast, too soon).

All suspected stress fractures should be evaluated and followed by the medical officer. Treatment for stress fractures include:

- ◆ Reduction or avoidance of impact and load bearing activities.
- ◆ Partial weight bearing with crutches and advancing to full weight bearing when pain free.

This process typically takes two to four weeks. Stress fractures are usually not casted when strict non-weight bearing or partial weight-bearing instructions can be assured. The reconditioning process should include swimming or water exercises (such as deep water running) to maintain flexibility and aerobic endurance. A program of lower extremity strengthening exercises should be started as soon as tolerated.

True fractures require a period of immobilization which varies depending on the bone involved. However, after the cast has been removed, the extremity should undergo a reconditioning program.

After the weight-bearing restriction has been lifted, the individual can begin a reconditioning program for running. A return to running should ideally be initiated on a treadmill. This allows the individual to customize increases in duration and speed while monitoring pain at the stress fracture site. A typical “return-to-running” program is presented in Table 12-4.

Table 12-4. Return to Running Post Injury

Return-to-Running

Run on soft and even surfaces- treadmill/track

Run 5 minutes at a slow pace

Increase time by 2 minutes every other day

When running pain-free for 15 minutes, increase pace

Advance to figure-of-eight runs: begin at 100 yard intervals and progress to tighter turns

Gradually increase distance (see Chapter 4)

Resume regular running program

Common Mission and Training Related Injuries

Given the nature of the SEAL's occupation, it is not surprising that injuries occur during training and mission-related scenarios. Clearly, the type of injury will depend on the specific physical tasks and the environments under which the tasks are performed. Table 12-5 presents a brief summary of some of the anticipated and common injuries that may occur during mission-related platforms. Other than these platforms, many of the injuries are a result of activities all SEALs participate in, namely swimming and running.

Table 12-5. Musculoskeletal Injuries Associated with Mission-Elements

Platform	Description of Injury
Steel Decks:	Knee Cap Pain (Patellofemoral Syndrome) Shin Splints Low Back Pain
High Speed Boats:	Knee Sprain with Effusion Back Pain Quadriceps Strain Tendonitis below Knee Cap (Patellar)
Parachute Jumps:	Fractures Patellar Tendonitis Low Back Strain/Sprain Muscle Strain
Confined Space (Submarine):	Header (Head Blow) Shin Contusions
Troop Transport:	Shin Splints
Rappelling/Rock Climbing:	Rope Burns Elbow Tendonitis Abrasions of the Fingers Biceps Tendonitis Back Strain Shoulder Sprain
Fast Roping:	Deep Heel Bruises

Swimming

Swimming is a non-impact activity involving maximum tension on the muscle-tendon unit. Most injuries result from overuse and over training, rather than from one traumatic event. Consequently, once an injury occurs, healing can prove difficult.

The older, experienced operator, despite a high skill level, faces the added challenge of tendons and joint capsules that are less resilient, muscles that take longer to warm up, and flexibility which is more difficult to maintain. All of these factors can lead to an increased risk of overuse and acute injury in this age group. The most common injuries arising from endurance swimming are sprains, strains and overuse injuries of the shoulder, knee and back.

Stroke-Associated Injuries

Freestyle, butterfly, and backstroke place a great amount of stress on the shoulder joint. Use alternate or bilateral breathing on freestyle and be sure to get plenty of roll on backstroke. Before beginning a butterfly set, be sure you are well warmed up. This will allow the shoulder to stay in a more neutral position during the activity of arm recovery and this neutral position helps prevent what is known as *“impingement syndrome”* (described later in Table 12-8).

Freestyle swimming and kicking with a kickboard places a great amount of stress on the low back because of hyperextension; doing the backstroke relieves the stress. A pullbuoy is also helpful as it raises the hips and allows the spine to assume a more neutral posture.

Kicking with fins may aggravate the knee (especially the knee cap) and result in a degenerative condition known as *patellofemoral syndrome*, which commonly afflicts athletic individuals (described later in Table 12-8).

The breaststroke kick helps balance the knee joint by increasing muscular tone on the inside of the quadriceps muscle, and serves to balance the effect that running has: increasing muscular tone on the outside portion of the quadriceps muscle. However, the breaststroke may actually intensify *iliotibial band syndrome* (described later in Table 12-8). Swimmers may need to avoid doing breaststroke if they feel increased pain over the outside of the knee.

Running and Hiking

Running and hiking work large muscle groups and enhance cardiovascular fitness in a short period of time. Hiking transmits a force to the spine of approximately three times load-bearing weight. Running transmits an impact force to the spine of up to five times load-bearing weight. These forces are minimized with good body mechanics, shock-absorbing shoes and cross-training for overall fitness. Table 12-6 outlines common running injuries.

Table 12-6. Common Running Injuries

Name of Injury	Description of Injury
Plantar Fasciitis	Inflammation and tightness of thick fibrous band on sole of foot.
Achilles Tendonitis	Inflammation of calf tendon or “heel cords” especially at insertion into heel.
Iliotibial Band Rub	Pain on outside or lateral aspect of knee or high on outside of hip.
Bursitis	Inflammation or irritation of various bursal sacs about inner or medial portion of knee, or behind the heel of the foot.
Shin Splints	Pain along medial aspect of lower third of tibia, worse in morning, resolves after warming up. Resolves with cooling down after running.
Back Strain/Sprain	Results from impact loading of spine.

Knee Sprains

A complete discussion of knee injuries is beyond the scope of this text. Medial and lateral collateral ligament sprains can be placed in a range-of-motion (ROM) brace to allow early flexion and extension while protecting the damaged ligament.

A knee immobilizer brace that extends and immobilizes the knee straight out should be used with caution. Within 72 hours of using this type of brace, the thigh muscle is weakened and atrophied (muscle wasting as a result of disuse). However, this type of brace must be used with patella (knee cap) fractures and patellar dislocations. While in this brace, strengthening exercises should be started as early as possible to avoid muscle atrophy.

Ankle Sprains

Ankle sprains are ideally treated in an aircast or similar splint. Ice, cross friction massage, partial weight-bearing, and early range of motion is allowed while protecting the injured ligament. Some severe sprains may require surgical intervention.

Overtraining Syndrome

The most common physical conditioning error for the SEAL operator is overtraining. Overtraining is exactly what the word implies, a condition caused by:

Too Much Physical Activity

Physical training for the operator differs from programs designed for elite athletes. The athlete in professional or college sports has an off-season to rest injured muscles and tendons, utilize physical therapy, maximize strength and flexibility, and finally cycle back into his sport. The SEAL team operator has no such luxury and training is a full time job. Typically he trains to peak levels year round. It is this repetitive, peak performance conditioning schedule that may lead to overtraining and overuse injuries.

The **OVERTRAINING SYNDROME** can present with a wide range of physiologic or psychological symptoms which vary widely among individuals (See Table 12-7). Overtraining is generally associated with endurance sports such as swimming or running.

There is no good laboratory or biochemical marker for overtraining syndrome. The **BEST INDICATORS** are resting heart rate in the morning and assessment of mood. Resting heart rate taken daily just before getting out of bed, and monitored over time will give some indicator of fitness as well as fatigue. Individuals who are overtrained will show a resting heart rate which is 10-15 beats per minute higher than baseline when measured

over a period of several days. A day or two of abstaining from physical activity should show a return to baseline. The operator who continues endurance activities despite the baseline elevation in heart rate will only become more overtrained.

Table 12-7. Characterization and Symptoms of Overtraining Syndrome

Major Symptoms of Overtraining	
Decreased performance and muscle strength	Decreased Capacity to make decisions
Burn-out or staleness	Difficulty with concentration
Chronically fatigued	Angry and irritable
Lacking motivation	Muscle soreness
Disturbances in mood	Increased distractibility
Feelings of depression	Difficulty sleeping
Change in heart rate at rest, exercise and recovery	Increased susceptibility to colds or other illnesses

Changes in mood or mood swings may also be a signal that the individual is overtraining. Little data exist on mood assessment in the SEAL community. Typically, assessment of mood is accomplished with questionnaires. However, individuals who are overtraining and give an honest assessment of mood will consistently report feelings of frustration, anger, depression or an inability to feel anything at all.

Cross-training, rest days, monitoring of morning heart rate, mood assessment, and taking time off from certain physical activities will reduce overtraining errors.

Overtraining differs from “overwork,” which is the temporary deterioration of performance capabilities due to an increase in the volume or intensity of training. Overwork is what typically happens to BUDS students. Physical and mental performance deteriorates in the most demanding parts of the training schedule, only to rebound quickly as the schedule lightens up. Unlike overtraining, the overworked individual is able to show an increase in physical performance when faced with a greater workload or physical challenge.

When to Seek Medical Care

Table 12-8 provides the symptoms, preventive measures, and selected treatment modalities for common training and mission-related musculoskeletal injuries. This list is presented for information and to help you determine whether you need to seek medical treatment. However, there are numerous conditions which demand immediate medical attention.

Conditions Requiring Immediate Evaluation by Medical Personnel:

- ◆ Back pain that radiates into the thigh, leg or foot.
- ◆ Severe pain.
- ◆ Numbness.
- ◆ Joint dislocation.
- ◆ Suspected fracture.
- ◆ Any lower extremity injury in which the individual is unable to bear weight.
- ◆ Pain which limits activity for 3 to 5 days.
- ◆ Any hip pain which causes a limp.

Table 12-8. Symptoms, Prevention, and Treatment of Common Training- and Mission-Related Injuries

Injury	Symptoms	Prevention	Treatment
Plantar Fasciitis	Pain in sole of foot just in front of heel; stiffness in sole with first steps of morning.	Stretch Achilles and foot after runs, hikes; massage sole of foot; firm shoes; 1/4" heel lift; arch supports.	Stretch the Achilles tendon and foot on incline board; tape sole instep; massage, ice sore spot; place 1/4" heel lift in shoes.
Metatarsal Stress Fracture	Pain in long bones of foot, especially 2nd or 3rd; worse with weight bearing; aches at night.	Avoid training too much, too fast, too soon; take care when transitioning to new training surfaces (grass to asphalt); different footwear (old shoes, new boots).	Decrease amount of running or hiking; avoid full weight-bearing, use crutch or cane; seek medical evaluation.
Shin Splints	Pain at lower third inner tibia; worse with first steps of running or hiking; usually after long or hard runs or hikes.	Good shoe/boot wear; stretch before and after runs/hikes; pronators (flat feet) should use arch supports.	Ice to painful area before and after run, hike; ankle strengthening exercises, calf stretches, arch supports; medical evaluation for pain longer than 12 days.
Iliotibial Band Rub (ITB)	Pain at outside portion of hip or knee; gets worse several minutes into run.	ITB stretches; discard broken down shoes; use running shoes with wide heel base; check leg length differences.	Ice to painful sites. ITB stretches. Hamstring and quad stretches. Heel lift for leg length difference.

Table 12-8. Symptoms, Prevention, and Treatment of Common Training- and Mission-Related Injuries

Injury	Symptoms	Prevention	Treatment
Muscle Cramps	Sudden severe pain in muscle belly, causing stiffness and loss of motion.	Maintain hydration/ acclimatization protocols; stretch at first hint of muscle tightness.	Grasp and tightly compress muscle belly with both hands; stretch muscle to maximum tolerable length until cramp resolves.
Achilles Tendonitis	Pain at back of heel along heel cord; worse with running and climbing.	Incline board stretch of Achilles; over-the-counter arch supports; stretch after all runs.	Ice for 15-20 minutes, every hour when possible; incline board stretch; cross friction massage.
Patellofemoral Syndrome	Knee pain localized under or around the knee cap; worse with going up/down hills or after prolonged sitting.	Quadriceps stretching/ strengthening exercises; hamstring and ITB flexibility exercises; check foot for biomechanical abnormalities (over pronation).	Ice and range of motion to acute injury; NSAIDs for 5 to 7 days; stretching/strengthening program. Arch supports or insert for over pronators.
Rucksack Palsy	Weakness, pain, and/or numbness of upper extremities or shoulders.	Correct load distribution; adjustment of straps as needed. Correct padding.	Avoid heavy load-bearing for 2 to 3 weeks; NSAIDs for 5 to 7 days.
Foot Blisters	Localized pain and redness: "hot spots caused by friction rub; clear fluid vesicle layer.	Shoe insoles (Spenco) Adaptive training to toughen skin; Change wet socks; Moleskin to blister-prone areas.	Cover blister with clean bandage and/ or moleskin; apply antiseptic to unroughen blister.

Table 12-8. Symptoms, Prevention, and Treatment of Common Training- and Mission-Related Injuries

Injury	Symptoms	Prevention	Treatment
Ankle Sprain	Pain, swelling, loss of function after turning the ankle.	Ankle stretching and flexibility exercises, ankle braces.	If unable to bear weight, seek medical evaluation. Ice 20 min. every hour; compression wrap from toes to lower leg; leaving no gaps. Elevation: elevate foot 18" off ground; motrin, aspirin for pain; partial weight bearing using cane or crutch; seek medical evaluation for pain lasting longer than 3 days.
Medial Epicondylitis	Pain at inner bony aspect of elbow; worse with wrist extension.	Caution with aggravating factors: narrow-based hand placement for push-ups or wrist extension under resistance; generalized wrist-strengthening program.	Ice to bony prominence; wrist stretching/strengthening exercises; cross friction massage; avoid aggravating factors.
Heat Stroke	Hot, dry, flushed skin, high body temperature, altered level of consciousness, weakness, incoordination.	Hydration, stepwise acclimation to environmental conditions.	LIFE THREATENING MEDICAL EMERGENCY. Replace fluids; if possible, cool water immersion in the field; ice packs to arm pits, groin, temple; transport immediately to medical facility.
Heat Exhaustion	Cool, damp skin; nausea, weakness, fatigue, poor concentration.	Maintain hydration, during exercise in all weather; avoid Black Flag conditions.	Remove excess clothing, replace fluids, cool body with water immersion, ice packs, transport to medical facility.

Chapter 13

Harmful Substances that Affect Performance

SEALs and other elite athletes are always looking for ways to improve their physical performance and gain a competitive edge to enhance their success in missions or competition. Often there is a temptation to seek other ways of increasing your capabilities, including trying various ergogenic agents or chemical substances, either natural or man-made, that promise to give an edge. This chapter reviews some of those chemicals that may give you a temporary edge, but the minor improvements you might see in the short-term can be harmful in the long-term. The goal of this chapter is to inform you of the detrimental effects and the legal consequences of using chemicals as performance enhancers. This chapter is not intended to support or promote the use of these chemicals for improving your performance.

Anabolic/Androgenic Steroids

Anabolic/Androgenic steroids, hereafter referred to as **AAS**, have been used by athletes to improve performance for more than 30 years. The non-medical use of AAS is widespread among athletes engaged in power sports such as power-lifting, bodybuilding, football and rugby. Their popularity stems from their perceived contribution to increase muscle bulk and strength and to improve competitiveness. There are more than one million estimated users of AAS in the United States alone. Approximately 2% of athletes between the ages of 10 and 14, and 5% to 10% of high school athletes have used AAS, even though their use is prohibited. In addition, approximately 5% of college athletes currently use AAS. Because of legal and administrative issues it is difficult to estimate the number of Olympic and professional athletes currently using the drugs. However, a number of Olympic Gold Medalists have had their medals withdrawn for using such substances. The

use of AAS for improved competitiveness violates ethical principles and is strictly prohibited by the military services as well as the United States Olympic Committee (USOC) and other national sports governing bodies.

How do Anabolic Steroids Work?

AAS are synthetic derivatives of the hormone testosterone, which is responsible for the development of male characteristics. The pituitary gland in the brain controls the production of testosterone in the male testes. Testosterone has both androgenic (masculinizing effects) and anabolic (tissue-building) properties. The main functions of testosterone in an adult are to:

- ◆ Promote secondary male sex characteristics, such as hair patterns and deepening of voice.
- ◆ Increase muscle mass.
- ◆ Initiate and maintain sperm production.

Anabolic steroids were developed by structurally altering testosterone to reduce its breakdown, and to maximize its tissue-building (anabolic) effects. The more commonly used anabolic steroids are listed in Table 13-1. This class of steroids was first used therapeutically to treat certain disorders of the blood, bone mass deterioration, protein wasting states, and as a replacement therapy for male children deficient in testosterone.

AAS should not be confused with corticosteroids which act as anti-inflammatory agents and are used to treat a variety of medical conditions.

Table 13-1. Commonly Used Anabolic/Androgenic Steroids

Generic Name	Street Name
Bolasterone	
Boldenone	Vebonol
Clostebol	Steranabol
Dehydrochlormethyltestosterone	Turnibol
Fluoxymesterone	Android F, Halotestin, Ora-testryl
Mesterolone	Androviron, Proviron
Metandienone	Danabol, Dianabol
Metenolone	Primobolan, Primonabol-Depot
Methandrostenolone	Dianabol
Methyltestosterone	Android, Estratest, Methandren
Nandrolone	Durabolin, Deca-Durabolin
Norethandrolone	Nilevar
Oxandrolone	Anavar
Oxymesterone	Oranabol, Theranabol
Oxymetholone	Anadrol, Nilevar, Anapolon 50
Stonozolol	Winstrol, Stroma
Testosterone	Malogen, Malogex, Delatestryl
Human Growth Hormone	Human Growth Hormone

How Anabolic Steroids Alter Metabolism

In a progressive weight training program, muscles are challenged to grow in size and strength in order to meet the increasing workload placed upon them. The structure of muscle consists chiefly of protein. Strength and size gains are achieved primarily by increasing the amount of protein inside the muscle. Protein requirements of the human body are determined by a complicated and difficult procedure called nitrogen balance. The body must ingest an adequate supply of protein in the diet to process, absorb, and retain nitrogen to support the weight training.

The stress of intensive strength training induces a catabolic state. In this state, muscle protein is broken down, but a state of anabolism or muscle protein formation follows. By an unknown mechanism, AAS enhance the anabolic processes. Anabolic steroids improve the body's nitrogen balance by reversing the catabolic state; thus muscle protein synthesis is supported. AAS are also believed to directly stimulate the growth of new protein within muscle cells and the cells of other tissues. A detailed description of protein needs is provided in *The Navy SEAL Nutrition Guide*. In brief, the daily requirement for protein is 0.6 to 0.8 grams per pound of body weight. Protein intakes in excess of 0.8 grams per pound do not cause an increase in protein stores, but such intakes do increase the work of the kidney. The kidneys are responsible for excreting the waste products from digestion of excess protein.

Purported Beneficial Effects of Anabolic Steroids

There are several purported effects of AAS which may be beneficial to athletes. The first is an increase in lean body mass. In muscle cells this would result in an increase in production of proteins responsible for muscle contraction, energy production and energy storage. The second is strength. AAS may regulate the movement of calcium from within the cells, which could lead to an increase in the speed and force of contraction. Another potential benefit of AAS is an increase in aggression which may allow the athlete to do more work. At times this may be desirable whereas in other situations it may actually compromise a mission. Overall, the potential beneficial effects of anabolic steroids include:

- ◆ Increased muscle size.
- ◆ Increased muscle strength.
- ◆ Increased aggression.
- ◆ A perception of improved performance.
- ◆ Increased motivation.
- ◆ Decreased fatigue.

Adverse Effects of Anabolic Steroids

The use of anabolic steroids is strongly associated with numerous undesirable effects, many of which may not be predictable on the basis of the dose or frequency with which they are used. These potentially dangerous substances are usually taken without supervision, although this is illegal, and there have been many reports of serious illness or deaths resulting from their use. AAS may falsely increase the perception of strength and cause an individual to lift heavier weights than he should. This often results in torn muscle and ruptured tendons, in particular tears of the biceps and deltoids, because **the strength of muscles increases more rapidly than the strength of tendons**. The immune system may be impaired, but this abnormality may not be detected until after its use. Importantly, transmission of hepatitis B and AIDS can occur from needle or drug sharing. Various cancers have also been associated with AAS use. Liver, cardiovascular, hormonal, reproductive and nervous systems are most affected, but other systems may also be adversely affected.

The most frequently reported negative effects are listed in Table 13-2. Many of these are reversible when steroids are discontinued, but some can be permanent or irreversible. If used in young athletes, these agents limit final height because of the early termination of bone growth. Clearly, the health risks far outweigh any benefits anabolic steroids may confer. The most common problem includes liver dysfunction. This serious medical problem occurs frequently in users of oral AAS and causes jaundice. Peliosis hepatitis, a condition where blood filled cysts develop within the liver, has also been reported.

The cardiovascular effects of AAS in men and women include high blood pressure, increases in serum cholesterol concentration and serum LDL (the bad cholesterol), and a decrease in serum HDL (the good cholesterol). Heart attacks, strokes, and blood clots in the lungs have also been reported in AAS users.

The hormonal effects of AAS use in the male include decreased natural testosterone production, decreased sperm count, production of abnormal sperm and shrinkage of the testes. Breast tissue enlargement is also common, as are acne, glucose intolerance, and baldness. Women AAS users have slightly different hormonal responses, including thickening of the vocal cords with resultant deepening of voice, male pattern baldness, facial hair growth and enlargement of the clitoris, all of which are irreversible. Breast tissue shrinkage, menstrual irregularities, infertility, glucose intolerance and acne are also common in women who use AAS.

Perhaps the most significant short-term adverse effects are the psychologic changes associated with AAS use. For both men and women AAS users, increased aggression, rage reactions (“roid rage”), altered libido, anxiety and panic disorders, psychosis (“bodybuilder’s psychosis”), depression, mania and addiction have been noted. Again, these effects are undesirable for tasks required by SEALs. It is extremely important to note that:

Many of the side effects may cause

permanent impairment, and some are potentially, if not outright, lethal.

Table 13-2. Adverse Effects of Anabolic Steroids in Men: Physiologic and Psychological

Physiological Effects	
Irreversible	
Breast enlargement	Atrophy of the testicles
May Be Reversible	
Decreased sperm production	Accelerated baldness
Decreased testosterone levels	Elevation of cholesterol
Liver tumors	High blood pressure
Acne	Liver dysfunction
Psychological Effects	
Irritability	Depression
Mood swings	Addiction
Mania	Psychosis
Excessive aggressiveness	

Legalities of Steroid Use

There are also legal ramifications associated with AAS use. Since early 1991, AAS and related compounds have been classified as drugs controlled by the Food and Drug Administration. These drugs have a high potential for physical and psychological dependence as well as their catabolic effects on various body systems. Transportation or distribution of these agents is punishable by fines of up to \$500,000.00 and/or a prison sentence of up to 15 years. The military, as well as most sports governing bodies, (IOC, USOC, NCAA, NFL), ban the use of AAS. Users who are detected using such agents face significant penalties.

AAS screening is now performed in the military along with routine random drug screening. Oral AAS can be detected by urine drug screening from 2-14 days after use. Some forms may be detected for weeks to months after injection. There is zero tolerance for possession and use of AAS in the military, unless appropriately prescribed by medical personnel. Any violation would be punishable under Article 92 of the Uniform Code of Military Justice (UCMJ). If found guilty, that individual may also be processed for administrative separation from the military.

Medical Uses of Corticosteroids

As stated previously, AAS should not be confused with corticosteroids. Corticosteroids, or glucocorticoids, are a category of synthetic hormones used to restrain inflammation and to control itching. They are commonly used topically for skin disorders, and given by injection into joints which are inflamed. Corticosteroids have been classified by the USOC as subject to restrictions; a physician must declare the intent to treat prior to a competition.

Other Harmful Chemicals

Growth Hormone

Human growth hormone (hGH) is a hormone produced in the brain. The hormone is commonly used to increase the height of very short children and until recently to increase strength in the elderly. Athletes have been known to use hGH at a black market cost of about \$2,000 for an 8-week course. The known effects of hGH in the athlete are shown in Table 13-3.

Table 13-3. Physiologic Effects of Growth Hormone

Increases muscle mass

Increases fat breakdown for energy

Conserves blood glucose and muscle glycogen storage

Increases height in the skeletally immature individual

Increases size of hands, feet, and jaw

Enhances healing of musculoskeletal injuries

Unfortunately, the increase in muscle mass does not increase muscle strength as much as strength training. No increase in height has been seen in a fully grown person, however, hGH may increase hand, foot, jaw and body size. There is little known about the adverse effects of hGH use in the normal athlete, but the skeletal muscle growth may be abnormal and therefore the muscles may be weak. Given that hGH use is banned by the military, as well as the IOC, NFL, NCAA and most sports governing bodies, it should not be used.

Clenbuterol

Clenbuterol, a drug used by veterinarians to increase muscle mass in livestock, is being used by many athletes, primarily those in strength-related sports. However, increases in muscle strength have not been shown in humans. In addition, there are numerous adverse side effects, including rapid heart rate, muscle tremors, headaches, nausea, dizziness, fever and chills. Although technically classified as a β_2 -agonist, it is officially considered an anabolic agent by the USOC, and is thus on their list of prohibited substances.

Stimulants

Stimulants are agents which increase arousal of the central nervous system (CNS). These agents are used medically in the treatment of various conditions, including depression, narcolepsy (sudden and irresistible onset of sleep), and in the treatment of diseases of the bronchial tubes. Athletes often abuse a number of stimulants because they think their performance will improve. Most stimulants are banned by the military as well as most sport governing bodies; these agents are also measured in routine random drug screening tests. The major classes of CNS stimulants are:

- ◆ Amphetamines
- ◆ Ephedrine

◆ Caffeine

This section will discuss only those agents which are illegal and can produce harmful effects.

Amphetamines

One class of stimulants is the **Amphetamines**. The term amphetamine also includes methylamphetamine, dimethyl-amphetamine, and benzylamphetamine which are metabolized to amphetamine after ingestion. In the 1960's, these drugs were widely used by athletes in the belief that they improved strength and endurance. Stimulants such as amphetamines and many over-the-counter amphetamine “look alikes” have pronounced effects throughout the body. Taking these agents will result in the physiologic and psychological effects noted in Table 13-4 and Table 13-5. As can be seen, these effects are the same ones which occur normally without stimulants when you are asked to undertake dangerous missions.

Table 13-4. Reported Physiologic Effects of Amphetamines

Increases heart rate

Increases cardiac output

Elevates blood pressure

Increases conversion of glycogen to glucose

Elevates serum glucose

Elevates serum free fatty acids

Dilates blood vessels in muscles

Constricts blood vessels in the skin

Increases muscle cell excitability

Amphetamines can mask symptoms of fatigue. They may restore reaction time in a weary athlete, but cannot improve reaction time or diligence in a well rested and motivated athlete. The potential beneficial effect is most marked when performance is reduced by fatigue or lack of sleep.

Exercise itself induces these same effects, so amphetamines have not been shown to make a net contribution to the physiological mechanisms which support athletic performance. They clearly make no difference in maximal aerobic capacity, but there is some evidence for small increases in speed and the time it takes to fatigue in endurance events. It could be that the primary performance enhancement benefit rendered by amphetamines lies in their psychological effects as listed in Table 13-5.

Table 13-5. Psychological Effects of Amphetamines

Delayed onset of the sensation of fatigue

Increased alertness

Mood elevation

Increased aggression

Improved self-confidence

Suppression of inhibitions

Perhaps more so than with many drugs, the use of amphetamines is associated with detrimental side-effects that cannot only erode athletic performance, but can also harm health and threaten life. These are listed in Table 13-6. Because of these side-effects and the illegality of their use, these drugs must be avoided.

Table 13-6. Adverse Effects of Amphetamine Use

Nervous System Effects		
Acute Effects	Irritability	Confusion
	Insomnia	Paranoia
	Restlessness	Delirium
	Dizziness	Uncontrolled Aggression
	Headache	Dry Mouth
	Vomiting	Abdominal Pain
Chronic Effects	Uncontrolled Involuntary Movements	Addiction
	High Blood Pressure	Cerebral Hemorrhage

Ephedrine and Pseudoephedrine

Ephedrine, and its most notable derivative, pseudoephedrine, are adrenaline-like CNS stimulants found in many over-the-counter cold and hay fever preparations as well as in many herbal products, in particular the herb known as Ma Huang. Like clenbuterol, ephedrine is a β -agonist, and has properties similar to that of amphetamines. It is often combined with caffeine. At doses higher than found in over-the-counter medications, restlessness, muscle tremors, anxiety, and headaches are frequently produced. Ephedrine is not widely used in sports to improve performance and there is no scientific evidence that it does. However, many people have used ephedrine and Ma Huang to lose weight through an increase in resting metabolic rate and metabolism of fat. Recently a number of people have died from drinking tea containing ephedrine. Given that it is banned by the OSOC and a potentially life-threatening agent, it should not be used.

Erythropoietin

Erythropoietin (EPO) is used by endurance athletes to improve performance. One type of EPO, called rEPO or rhEPO, is used to treat a number of blood diseases. Athletes use rEPO because it increases the red blood cell count by stimulating red blood cell production and speeding red blood cell release from the bone marrow to the blood stream. The red blood cells carry oxygen to the muscles, so more red cells mean more oxygen. The

effects of rEPO are actually similar to those seen in an athlete who trains at altitude. In order for these changes to occur, the athlete must have an adequate iron intake and maintain an aerobic training schedule.

The increase in red blood cell production can cause a number of significant adverse effects. High blood pressure, a flu-like syndrome, and a sluggish bloodflow are the most common. Bloodflow becomes sluggish when the percentage of red blood cells reaches 55%. Normal ranges are 40% to 48% in men and 36% to 45% in women. Sluggish blood flow causes a variety of complaints, including headache, dizziness, ringing in the ears, visual changes, and chest pain. Other possible complications are heart attack, seizure, or stroke due to a blockage of blood flow. Up to 18 deaths due to rEPO have been reported in cyclists. The use of blood doping or rEPO is prohibited by all sport governing bodies as well as the military.

DHEA

DHEA, or dehydroepiandrosterone, is a hormone released by your adrenal glands into your bloodstream each morning; from there it travels to other tissues and is converted into small amounts of testosterone (estrogen for women). It has been shown that levels of DHEA decline with age, and this finding has created a sensation among the manufacturing world. Although DHEA has been available for decades, it has only been on the market since about 1994. It is now being touted as the miracle drug of the 21st century. There is no question that it is a miracle drug to the companies producing and selling it, but the true benefits in humans has not been determined. The various claims being advertised for DHEA include:

- ◆ Lengthening of life
- ◆ Prevention of cancer, heart disease, and osteoporosis
- ◆ Burning of fat stores
- ◆ Stimulate libido
- ◆ Boosts energy levels and mood
- ◆ Enhances immune system

None of these claims have been demonstrated, and there are a number of reasons why it may be hazardous. As stated previously, DHEA is a hormone and it can be converted to testosterone. Increased testosterone levels could increase your risk of prostate cancer. The other potential dangers of DHEA will unfold as more research is conducted, and people who are taking it regularly are followed. To date it has not been banned by the USOC, but that may be only because it is so new on the market.

Summary

In conclusion, none of the chemical agents discussed above offer any guarantee that your performance will improve. However, there is a good chance you could compromise your military careers by using them. The benefits of these agents are limited and the potential harmful effects are clear. Our advice is to keep up with your training according to the methods described in other chapters.

Chapter 14

Other Training-Related Issues

This chapter presents other issues important to SEAL training, but may only pertain to certain subgroups of SEALs. For example, not all teams train for Winter Warfare and many individuals do not currently qualify as “High Mileage” SEALs (but will in the future). Also included is a section on nutritional ergogenic agents, since many athletes use these products in an effort to improve performance.

Winter Warfare Training

Winter warfare imposes some specific physical training demands on SEALs. During training and deployment, winter warfare operations challenge an individual’s skill in protection from environmental factors and ability to move efficiently over snow and ice. Thus, cross country skiing is recommended for those involved in winter warfare operations. This section reviews training issues specific to the winter warfare mission.

Training for Skiing

A high skill level is essential if use of skis is contemplated. Under most operational conditions, cross country skiing provides the highest degree of non-mechanized mobility for travelling over snow and ice. Skiing becomes a very efficient form of man-powered transportation during long transits over flat terrain. However, the advantages of skiing only become apparent after acquisition of specific skills and fitness.

It is extremely easy to sustain a serious immobilizing injury while skiing heel free in non-release bindings and floppy loose boots. The potential for injury is magnified further when the skier is loaded down with gear. Thus, the operator participating in winter warfare must be a competent skier.

The overall fitness level of SEALs may be adequate for cross country skiing because fitness from running and aquatic training carry over to skiing. However, different muscle groups are used; thus SEALs should strive to customize their training programs in anticipation of winter warfare. Use of a ski machine does confer training specificity and assists with developing the coordination and muscle adaptations needed to ski efficiently. Other real training issues for skiing are skills and technique. There are several operational considerations to consider:

- ◆ Need to be able to stop and turn efficiently in a variety of snow and ice conditions.
- ◆ Need to be able to ski safely with a pack and weapons.
- ◆ Need to be familiar with gear modifications for maximum efficiency.

Turns, Stops, and Technique

Safe skiing with a pack demands aggressive unweighting and the use of parallel ski techniques. Forget about telemark turns while you are wearing a pack; the slow forward lunge required to initiate a turn in back-country snows while wearing a pack puts the skier in a vulnerable body position. This is an invitation to sustain a serious knee injury to the lead leg, particularly because of the extra weight transmitted to the leg due to wearing a pack.

Telemarking is useful when used to stop while traversing a hill. Instead of extending the uphill leg to initiate a downhill turn, extend the downhill ski and drift up into the hill. This maneuver is easy to control and is a useful tool for checking downhill speed while skiing heel free and wearing a pack.

Poles are essential tools for propulsion and balance while wearing a pack. It is important to use break-away wrist straps to prevent an injury to the arm or shoulder which can occur if the ski pole basket inadvertently catches on a stump or something else frozen solidly to the ground.

The High Mileage SEAL

Chronic overuse injuries and accumulated minor and major trauma to the musculoskeletal system have a cumulative effect on the “High-Mileage” SEAL approaching the age of 40. The most common chronic musculoskeletal injuries involve the neck, back, elbow, knee, ankle and foot. Table 14-1 outlines the sites and causes of these various chronic conditions. It also presents selected recommendations for treating these conditions. Poor flexibility can be a major contributory factor in all of these conditions. A lifetime program of flexibility, strengthening, and cross-training for aerobic conditioning is essential for minimizing chronic injuries and pain. In the event of an injury, early self-referral for evaluation is an essential part of avoiding chronic injury.

For those having recurrent problems or nursing old injuries, fitness can still be maintained and rehabilitation can proceed. Aerobic activities that may help include the stationary cycles, indoor swimming, a rowing machine, a ski machine, or a climber. However, it is most important to emphasize flexibility, with a specialized PT program that includes stretching. We believe that the Physical Fitness and PT Programs presented in Table 14-2 and Table 14-3 may help restore function if carried out regularly. However, you must remember not to push yourself too hard so as

to avoid a recurrence of previous injuries. Also, it is important to remember that you may need a longer time to recover than you did when you were 18. Listen to your body so it will be kind to you in the future.

Table 14-1. Sites, Common Causes of, and Recommendations for Chronic Musculoskeletal Pain

Site	Common Causes	Recommendations (After a Medical Evaluation)
Back	Ligament strain; instability; osteoarthritis; weak abdominal muscles; sacroiliac joint dysfunction; sciatica; poor flexibility.	Stretching program morning and evening; back and abdominal strengthening program; manipulations; avoid swimming with a kickboard and running until pain is manageable.
Neck	Ligament strain; Facet Syndrome; muscle strain; disc disease	Isometric stretch; avoid freestyle swimming until pain-free.
Elbow	Tendonitis; epicondylitis	Ice affected area; wrist and elbow stretching; avoid diamond push-ups until pain-free.
Knee	Patellofemoral Pain Syndrome; tendonitis.	Quad and hamstring stretching/strengthening exercises; avoid extra trips up and down stairs; avoid jumping activities until pain-free; try stationary cycling.
Shoulder	Impingement Syndrome; instability; rotator cuff tendonitis.	Rotator cuff stretching/strengthening exercises; ice shoulder after activity; avoid overhead activity, military press, butterfly stroke; do not swim train with paddles; breath on same side of injury during freestyle swimming.
Ankle	Old fractures with osteoarthritis	Ankle flexibility exercises; calf stretching; avoid load-bearing and long runs; Try stationary cycling.
Foot	Plantar Faciitis	Calf and foot stretching; heel lifts; steroid injection.

In the long run it is better to be conservative: injuries do not always go away. In fact, some lie dormant until you push just a bit too hard. Then it is too late. Seek medical care if there is any doubt, as your job depends on your health.

Table 14-2. Physical Fitness Program for High Mileage SEALs with Chronic Musculoskeletal Pain

Day of Week	Activities for the Day
Monday	PT/30 min Interval Work-Out (Rowing Ergometer)/Stretch
Tuesday	45 min Steady State Work-Out (Stationary Cycle)/Stretch
Wednesday	PT/45 min Fartlek Work-Out (Rowing Ergometer)/Stretch
Thursday	Cycle 15/Row 15/Cycle 15/Stretch
Friday	PT/30 min Slow Jog
Saturday and Sunday	Take one day off and use other day for low key training in whatever way you choose.
Two to Three Times/ Week	Circuit or Free Weight Training

Table 14-3. A PT Program for High Mileage SEALs with Chronic Musculoskeletal Pain

Exercises*	Repetition (#)	Total Time in Seconds
Jumping Jacks	25	60
1/2 Jumping Jacks	25 - 2 count	60
Up-Back-and Overs	5	60
Crunches (All Variations)	25-50	60
Push-Ups (Regular)	20	60
Torso Prone Stretch	2	30
Butterflies Stretch	2	30
ITB Stretch	2 each side	60
3 Way Hurdler's Stretch	2 each side	180
Swimmer's Stretch	2	30
Push-Ups (Regular)	20	60
Sit-Ups	20	60
Supine Back Stretch	1	30
Prone Superman	10 each side	60
Vee-Ups	30	60
Donkey Kicks	20 each side	60
Posterior Shoulder or Upper Back Stretch	2	30
Triceps Stretch	2 each side	60
Iliopsoas Stretch (Russian Dancers)	2 each side	60
Standing Quad Stretch	2 each side	60
Standing Toe Pointers	30	60
Gastroc/Soleus Stretch	2 each side	60

*All exercises (described in Chapter 7: Flexibility or Chapter 8: Calisthenics) should be done in order.

Nutritional Ergogenic Agents

Ergogenic agents are by definition, substances or techniques that enhance performance. Because SEALs are required to perform at a high level both mentally and physically, many are looking for substances or techniques to improve performance and provide “an edge”. To perform longer, to be faster, to be stronger, and to be leaner, if not a mission goal, are personal goals of many SEALs and elite athletes. People have been trying to accomplish these goals for centuries through the use of ergogenic agents. It is our goal to present information about certain products commonly found in retail stores or by mail order, that claim performance enhancing effects. For a detailed discussion refer to *The Navy SEAL Nutrition Guide*. Specifically, this section will provide information on:

- ◆ Nutritional Products Advertised as Ergogenic Agents.
- ◆ Protein-Carbohydrate Supplements.

Nutritional Products Advertised as Ergogenic Agents

This section lists many of the nutritional ergogenic agents sold by manufacturers with claims to “enhance performance” or have “muscle building” properties. Some have valid claims whereas others do not. It is often difficult to differentiate false claims from valid ones if you haven’t carefully researched each product individually. Many claims sound very scientific and convincing but, unfortunately, they are often false or unproven. For each agent described in Table 14-4, the claims, the usual dose used, and a comment are provided.

Table 14-4. Nutritional Ergogenic Agents

Agents	Claims	Dose	Comment
Choline	Enhances endurance performance.	400 to 900 mg daily as choline bitartrate or citrate. Foods rich in choline include egg yolk, meat, liver, and peanuts.	No benefit reported - not known to be harmful at above doses. Most claims based on theoretical possibilities.
Octacosanol-Wheat Germ Oil	Improves endurance capacity.	100 to 6000 mg daily with expected results in 4 to 6 weeks.	Some benefit reported.
Arginine, Lysine, and Ornithine	Stimulate growth hormone release.	Variable. Ornithine - 500 mg a day or 250 mg one to three times a day. Arginine - 500 mg one hour before meals and/or before workout. These items are sold separately or in combinations with varying amounts of amino acid content.	Ornithine - No benefit. Gastrointestinal disturbances are common. Arginine, Lysine - Some benefit reported.
Sodium Bicarbonate, ("Bicarb loading", "Soda loading")	Enhances anaerobic performance during high intensity exercise lasting 1 to 5 min.	0.3 grams of sodium bicarb per kg body weight mixed with 1 liter of water 1 to 2 hours before exercise.	Some benefit reported - Be careful...harmful if taken in large amounts. Discontinue use if abdominal cramps or diarrhea occurs.
Caffeine	"Fat burner", delays onset of fatigue, enhances performance.	4 to 9 mg/kg 30 mins to one hour prior to exercise.	Some benefits reported, but discontinue use if side effects noted (stomach pain, tremor) interfere with concentration or steadiness.
L-Carnitine	"Fat burner", delays onset of fatigue.	500 mg daily. Food rich in Carnitine include meat and dairy products.	Little to no reported benefit - not harmful at above doses. AVOID D-carnitine - A carnitine deficiency may occur.
Chromium Picolinate	Increases muscle mass, growth stimulating.	50 to 1000 µg/day as a dietary supplement. Foods rich in chromium include beer, brewer's yeast, oysters, mushrooms, meats, and whole grain cereals.	Some benefit reported.

Table 14-4. Nutritional Ergogenic Agents

Agents	Claims	Dose	Comment
Coenzyme Q ₁₀	Increases energy and cardiac performance. Potent antioxidant.	1.0 mg three times a day. Foods rich in CoQ ₁₀ include beef, eggs, and spinach.	No benefit reported in athletes.
Dibenzoyl/cobamamide - Coenzyme forms of B ₁₂	Anabolic and growth promoting.	500 mg daily in tablet form.	Little or no proven benefit - no harmful effects at given doses.
λ-Oryzanol and Ferulic Acid	Increases testosterone and increases lean body mass.	Variable, but commonly found in 50 mg per day doses.	Little or no proven benefit - no harmful effects at above doses.
Glandulars (ground up animal organs; usually testes, pituitaries and hypothalamus).	Will elevate testosterone levels. The "extra" testosterone will make you more build up more muscle and get bigger.	As a dietary supplement mixed with protein/carbohydrate powders.	Not recommended. Some products could be harmful.
Inosine	Energy enhancer; Increases endurance, strength, and recuperation.	500 to 1000 mg 15 min prior to exercise.	No. People with gout should avoid inosine. Dubious effects not worth the risk.
Branched Chain Amino Acids (BCAAs) - Leucine, Isoleucine, Valine	Anabolic and growth hormone stimulator; may protect against mental fatigue of exercise.	There are various products with different amounts of BCAA in them. Example: Leucine 800 mg daily, Isoleucine 300 mg, Valine 200 mg. Usually consumed prior to working out. Foods rich in BCAAs include turkey, chicken, navy beans, and other meats.	Some benefits reported.

Table 14-4. Nutritional Ergogenic Agents

Agents	Claims	Dose	Comment
Sapogenins - Smilax, Dioscorea, Trillium, Yucca, or Sarsaparilla	Increases muscle mass and lean body weight by increasing testosterone levels. A testosterone precursor.	Sublingual or capsular as directed. Use prior to workout and before bed.	Little benefit reported. Some products suspended in 18% alcohol. READ the label.
Tyrosine	Reverses cold-induced working memory deficit. Positive impact on stress-induced cognitive performance degradation.	75 to 150 mg/kg of L-tyrosine 1 to 2 hours prior to exposure.	Some benefits reported in SEAL cold weather operations. Branched chain amino acids should not be taken with tyrosine since they interfere with tyrosine's action.

Summary of Ergogenic Agents

Below are brief comments on various ergogenic agents, grouped by purported benefit or effect.

Agent	Comment
Delays Fatigue/Increases Energy Levels	
Caffeine	Some benefit reported
Choline	Theoretically beneficial - remains to be tested
Coenzyme Q ₁₀	No proven benefit
Inosine	Little or no proven benefit
Octacosanol	Some reported benefit
Sodium Bicarbonate	Some reported benefit
Tyrosine	Some benefit reported during SEAL cold weather ops

Agent	Comment
Fat Burners/Lean Body Mass Increaseers	
Carnitine	Little or no reported benefit
Chromium	Some benefit reported
I-Oryzanol/Ferulic Acid	Little or no benefit reported
Testosterone Enhancers	
Glandulars	Not recommended
Hot Stuff	Possible adverse effects
Smilax	Little or no reported benefit
Growth Hormone Releasers	
Arginine	Some benefit reported
Branch Chain Amino Acids	Some benefit reported
Lysine	Some benefit reported

Protein-Carbohydrate Supplements

Go into a retail or specialty store that caters to athletes and you may become overwhelmed by the number of different products available. One of the most highly visible and advertised group of products are the powdered protein and carbohydrate beverages. “Weight gaining”, “anabolic”, “muscle building” -- these are just a few of the various claims made by manufacturers. They do share one thing in common however: they are sold as supplements to your diet. These products are intended to fortify your diet to meet the nutrient demands of your body. In general, there are three basic reasons why people take supplements:

- ◆ Compensate for less than adequate diets or life-styles.
- ◆ Meet unusual nutrient demands induced by heavy exercise.
- ◆ Produce direct positive effects on performance

Your profession and life-style impose unique physical demands that require stamina, power, and strength. Consequently, your caloric (energy) expenditure is greater than the average person.

Supplements are a quick and convenient means for obtaining the nutrients you need. For example, some people find that after eating a normal breakfast they feel ill or nauseous during morning PT. If you can't tolerate exercising on a full stomach, then a powdered beverage may be the answer for your breakfast. You get the calories you need in the morning, but don't have that heavy feeling in your stomach. Remember that you may not need the full recommended serving size. Count the calories to suit your own energy requirements and goals.

It is also important to realize that it is not the supplement alone that leads to better performance. Success lies in addressing your goals and analyzing and adapting your diet to meet those goals. It will take some work on your part to calculate how much supplement, if any, you need to use. Read the labels and figure out how many calories you will expend before your next meal. Also, make sure you add up the vitamins and minerals you are getting from all the different supplements you are taking. Many products provide similar nutrients and you may be taking TOO much of one or several nutrients.

Another decision to make is whether or not to use a protein, carbohydrate, or combination beverage. Once again, it all depends on your goals. If you want to increase lean body mass through resistive training, then some protein may be the way to go. Remember that:

You only need 0.6 to 0.8 grams of protein per pound body weight per day.

This is equivalent to 105 to 140 grams for a 175 lb. SEAL. Keep in mind that there are food sources of protein that are very easy to come by and tend to cost much less money. For example:

- ◆ One 6 oz. can of tuna fish has 48 grams of protein.
- ◆ One 4 oz. breast of chicken has 36 grams of protein.
- ◆ One 8 oz. glass of milk (skim) has 10 grams of protein.

Chapter 15

Physical Fitness and Training Recommendations

The purpose of this final chapter is to provide a comprehensive training program that combines all the information presented in the preceding chapters. This chapter has been developed by group consensus, and attempts to address the specific needs of SEALs.

The SEAL Physical Fitness Program

The ultimate SEAL physical fitness program will incorporate all aspects of physical training. After an initial warm-up, the overall workout will include exercises to develop and/or maintain:

- ◆ Cardiovascular Fitness (Aerobic/Anaerobic Capacity and Power).
- ◆ Flexibility.
- ◆ Muscular Fitness (Strength, Endurance and Power).

Aerobic fitness includes conditioning runs or swims whereas anaerobic activities would include interval or fartlek runs/swims. Flexibility is improved by stretching, and muscular fitness by weight training, circuit training, or other such activities. The relative time spent on a particular aspect of fitness each day may vary, but every day incorporates exercises to improve or maintain: muscle strength, aerobic and anaerobic capacity, and flexibility. One point that has been stressed and should be remembered is that:

Strength and flexibility are closely linked.

Building strength tends to shorten muscles and limit flexibility; thus, stretching is essential for maintaining flexibility. The final recommendations are shown in Table 15-1. Some of the activities cannot accommodate the entire group, but rather must be done in smaller groups. For example, circuit weight training can be done in groups of 8 to 12, but not the entire team. These are recommendations, but alternate activities can be substituted. Table 15-2 provides some suggestions for alternative activities.

Table 15-1. The Navy SEAL Physical Fitness Program

Week Day	Activities for the Day
Monday	Stretch/1 circuit of O’COURSE/3 Mile Run/Stretch
Tuesday	PT/1.5 Mile Swim/Stretch
Wednesday	PT/4-5 Mile Run with Fartlek Workout/Stretch
Thursday	Run 3 Miles/Swim 1/Run 3/Stretch
Friday	Alternate 10 Mile Hike with Pack and Monster Mash
Saturday and Sunday	Take one day off and use other day for endurance training according to your preferences
Twice Each Week	2 Platoon hours with circuit/weight training

Table 15-2. Alternate Activities for a Fitness Program

Interval Sprints (Run or Swim)	Plyometrics	Total Body PT
Timed PRT	Cross Country Skiing	Bicycling
Running in Place	Pool Swim with Small Group (16/group)	
Jumping Rope	Rope Climbs for Grip Strength	

Physical training (PT) exercises are listed on two of the five days in the Recommended SEAL Physical Fitness Program. The PT program recommended for you (shown in Table 15-3) is called a Basic PT Program, and it will typically serve as a prelude to the main, more rigorous, activity(ies) of the day. It includes warm-up activities to loosen your muscles and exercises to increase your range of motion, muscle strength, muscle endurance, and power. Depending on the number of repetitions you perform, this PT can take as little as 10 or as many as 40 minutes.

Table 15-3. Basic Physical Training (PT) Activities for Warm-Up, Flexibility and Strength

Exercises*	Repetition (#)	Total Time (Seconds)
Jumping Jacks	50	60
1/2 Jumping Jacks	50 - 2 count	60
Up-Back-and Overs	10	60
Crunches (All Variations)	60 - 100	60
Push-Ups (Regular)	30	60
Flutter Kicks	25	60
Butterflies Stretch	2	30
ITB Stretch	2 each side	60
3 Way Hurdler's Stretch	2 each side	180
Swimmer's Stretch	2	30
Push-Ups (Diamond)	30	60

Table 15-3. Basic Physical Training (PT) Activities for Warm-Up, Flexibility and Strength

Exercises*	Repetition (#)	Total Time (Seconds)
Sit-Ups	30	60
Push-Ups (Wide Stance)	30	60
Supine Back Stretch	1	30
Torso Prone Stretch	2	30
Prone Superman	10 each side	60
Vee-Ups	30	60
Donkey Kicks	30 each side	60
Hand to Knee Squat	10	30
Posterior Shoulder or Upper Back Stretch	2	30
Triceps Stretch	2 each side	60
Iliopsoas Stretch (Russian Dancers)	2 each side	30
Standing Quad Stretch	2 each side	60
Standing Toe Pointers	30	60
Gastroc/Soleus Stretch	2 each side	60
Pull-Ups	MAX	60
Dips	MAX	60
Rope Climbs	1	-

*All exercises (See Chapter 7: Flexibility and Chapter 8: Calisthenics for descriptions) should be done in order.

For those interested in a more intensive PT program, a sample Total Body PT program is included for you. Alternatively, you can increase the number of repetitions of the exercises in the “basic” PT program. Both programs are very versatile, yet complete with respect to the whole body nature of the work-out.

Table 15-4. Total Body Physical Training (PT) Activities for Warm-Up, Flexibility and Strength

Exercises*	Repetition (#)	Total Time (Seconds)
Jumping Jacks	50	60
1/2 Jumping Jacks	50 - 2 count	60
Up-Back-and Overs	10	60
Crunches (All Variations)	60 - 100	60
Push-Ups (Regular)	30	60
Flutter Kicks	25	60
Dirty Dogs	20 each side	60
Butterflies Stretch	2	30
ITB Stretch	2 each side	60
3 Way Hurdler's Stretch	2 each side	180
Swimmer's Stretch	2	30
Push-Ups (Diamond)	30	60
Sit-Ups	30	60
Push-Ups (Wide Stance)	30	60
One Legged Squat	10 each side	60
Supine Back Stretch	1	30
Torso Prone Stretch	2	30
Prone Superman	10 each side	60

Table 15-4. Total Body Physical Training (PT) Activities for Warm-Up, Flexibility and Strength

Exercises*	Repetition (#)	Total Time (Seconds)
Vee-Ups	30	60
Donkey Kicks	30 each side	60
Hand to Knee Squat	10	30
Posterior Shoulder or Upper Back Stretch	2	30
Triceps Stretch	2 each side	60
Iliopsoas Stretch (Russian Dancers)	2 each side	30
Standing Quad Stretch	2 each side	60
Standing Toe Pointers	30	60
Gastroc/Soleus Stretch	2 each side	60
Repeat Starting at Crunches (2 - 3 times)		
Pull-Ups	MAX	60
Dips	MAX	60
Rope Climbs	1	

*All exercises (described in Chapter 7: Flexibility or Chapter 8: Calisthenics) should be done in order.

You should also include strength training at least twice per week. Details of a strength program are provided in Chapter 6.

A Physical Fitness Program for Confined Spaces

Maintaining fitness aboard a ship or submarine is possible. However, it requires motivation and discipline because usually the team spirit is missing. It is critical to maintain fitness so that when you reach your destination you have not become detrained. Table 15-5 presents a potential training program that could be followed on most ships. Most ships have stationary bicycles and rowing machines. However, if the ship has some other type of equipment, the schedule below could be modified to accommodate what equipment is available.

Table 15-5. Physical Fitness in Confined Spaces

Week Day	Activities for the Day
Monday	PT/30 min Interval Work-Out (Rowing Ergometer)/Stretch
Tuesday	45 min Steady State Work-Out (Stationary Cycle)/Stretch
Wednesday	PT/45 min Fartlek Work-Out (Rowing Ergometer, Jumping Rope)/Stretch
Thursday	Cycle 15/Row 15//Cycle 15/Stretch
Friday	Total Body PT
Saturday and Sunday	Take one day off and use other day for 60 minutes of low key training with whatever you choose
Two to Three Times/ Week	Circuit or Free Weight Training if Possible

A Physical Fitness Program for Coming Off Travel

When you first come back to shore or to your home base, you are not always in as good a physical shape as you were when you deployed. For this reason it is critical that you start back sensibly so as not to injure yourself. Both the PT and endurance components need to be modified so as to improve your overall fitness, not to put you in the doctor's office. Table 15-6 and Table 15-7 provide a reasonable Fitness and PT program for those coming off of travel. When you feel like you are back to your usual fitness level, then the Basic or Total Body Physical Fitness Programs can be started and/or worked into your schedule.

Table 15-6. A Re-Entry Physical Fitness Program

Week Day	Activities for the Day
Monday	Modified PT/2 - 3 Mile Run/Stretch
Tuesday	1 Mile Swim/Stretch
Wednesday	Modified PT/3 Mile Run with Modified Fartlek Workout/Stretch
Thursday	Run 1.5 Miles/Swim 1/Run 1.5/Stretch
Friday	Alternate 5 Mile Hike with Pack and Monster Mash with Buddy Carries
Saturday and Sunday	Take one or two days off according to how you feel and your preferences
Two to Three Times/Week	Circuit or Free Weight Training

Table 15-7. Re-Entry Physical Training

Exercises*	Repetition (#)	Total Time in Seconds
Jumping Jacks	25	60
1/2 Jumping Jacks	25 - 2 count	60
Up-Back-and Overs	5	60
Crunches (All Variations)	40 - 80	60
Push-Ups (Regular)	20	60
Flutter Kicks	15	30
Butterflies Stretch	2	30
ITB Stretch	2 each side	60
3 Way Hurdler's Stretch	2 each side	180
Swimmer's Stretch	2	30
Push-Ups (Diamond)	20	60
Sit-Ups	20	60
Push-Ups (Wide Stance)	20	60
Supine Back Stretch	1	30
Torso Prone Stretch	2	30
Prone Superman	10 each side	60
Vee-Ups	30	60
Donkey Kicks	20 each side	60
Hand to Knee Squat	10	30
Posterior Shoulder or Upper Back Stretch	2	30

Table 15-7. Re-Entry Physical Training

Exercises*	Repetition (#)	Total Time in Seconds
Triceps Stretch	2 each side	60
Iliopsoas Stretch (Russian Dancers)	2 each side	60
Standing Quad Stretch	2 each side	60
Standing Toe Pointers	30	60
Gastroc/Soleus Stretch	2 each side	60
Pull-Ups	MAX	60
Dips	MAX	60
Rope Climbs	1	-

*All exercises (described in Chapter 7: Flexibility or Chapter 8: Calisthenics) should be done in order.

Elimination of “Old” Exercises

As you may have noticed, some of your old favorites (or old foes) are no longer recommended. In May of 1994, a panel of experts convened to look at all of the different PT exercises currently in use by the SEAL community. A number of exercises were considered potentially harmful and were therefore eliminated. In addition, many exercises were modified to make them more effective (or potentially less harmful). Descriptions and diagrams for most of the exercises which are acceptable are provided in Chapters 7 and 8 (Flexibility and Calisthenics). Table 15-8 lists exercises that were eliminated and the reason for their elimination.

Table 15-8. Exercises Eliminated from SEAL PT

Exercise	Reason for Elimination
Windmills	Potential for injury to discs and lower back
Back Stretch	Potential for injury to cervical spine
Cherry Pickers	Potential for injury to discs and lower back
Cross-Overs (Hamstring Stretch)	Potential for injury to discs and lower back
Hand-to Toe Sit-Ups	Mechanical stress on back; no benefit to abs.
Standing Head to Knee	Potential for injury to discs and lower back
Standing Hamstring Stretch	Potential for injury to back
2 Person Thigh Stretch	Potential for injury to knee

A Short Flexibility Program

Flexibility exercises are an important physical fitness component and may add years to your operational life. For those who have been injured, the “high mileage” SEAL (see Chapter 14), or someone with naturally short muscles, a short flexibility program is provided in Table 15-9.

Table 15-9. Selected Stretching Exercises for Improving Flexibility - A Short Program

Body Position	Flexibility Exercises*	
Hold each for 15 to 30 seconds and perform two times on each side when appropriate.		
Standing:	Lateral/Forward Neck Flexion	Posterior Shoulder Stretch
	Upper Back Stretch	Triceps Stretch
Sitting:	Swimmer's Stretch	ITB Stretch
	3-Way Hurdler's	
Back:	Supine Back	Hipstretch
Stomach:	Torso Prone	Prone Quad
Kneeling:	Kneeling Lunge with Pelvic Tilt	Achilles Stretch
Standing:	Gastroc Stretch	Soleus Stretch

*All exercises are described in Chapter 7: Flexibility

The Navy SEAL Physical Readiness Test (PRT)

The Navy SEAL Physical Readiness Test (PRT) is conducted in one session in a continuous manner, with no less than two minutes or greater than 15 minutes rest between exercise, and no more than a 30 minute break between the run and swim. Failure to successfully complete all events constitutes failure of the PRT. The PRT events, in order performed, include:

- ◆ Pull-Ups.
- ◆ Sit-Ups.
- ◆ Push-Ups.

- ◆ 3 Mile Run.
- ◆ 0.5 Mile Pool Swim.

The first event, the pull-ups, has no time limit, whereas the sit-ups and push-ups have a three minute time limit. All three events are performed in clearly designated ways, and points are assigned to each event based on age and the number completed. The 3 mile run and 0.5 mile swim are timed events, and the time to completion and age are used to assign points. When all events have been completed, points for individual events are summed and an overall score is assigned. Table 15-10 provides a sample PRT test.

Table 15-10. PRT Score for a 34 year old SEAL

Event	Number or Time Completed	Points
Pull-Ups	18	80
Sit-Ups	105	85
Push-Ups	100	90
3 Mile Run	18:00	94
0.5 Mile Swim	15:00	90
Total Points		439

The greatest number of points for any event is 100; thus the highest possible composite score is 500. The overall score is used for classification purposes: you can fall into one of five categories:

- ◆ Outstanding 425 - 500
- ◆ Excellent 350 - 424
- ◆ Good 275 - 349
- ◆ Satisfactory 200 - 274
- ◆ Fail < 200 or < 40 for any event

In the example in Table 15-10, the overall score was 439; this would be rated as OUTSTANDING. Please refer to COMNAVSPECWARCOMINST 6110.1B for further information with respect to the Navy SEAL PRT and the tables describing points for each event.

Final Comments From: RADM Smith

This manual is a superb guide covering all the major focus areas required to maintain fitness as a SEAL. I offer as a final piece of SEAL culture, my version of "burn-out PT" in Table 15-11. The progression of the program is as follows: start at Stage 1 and cycle through the first set of each exercise, followed by the next sets. Next, move on to Stage 2 and use the same sequence. Begin with lower reps per exercise, with the goal of eventually completing the PT as set forth in Table 15-11. Those who have done it, know it is not what a modern fitness expert would necessarily approve of e.g., no stretching, (do it on your own time), over repetition of the same exercises, and several stomach exercises clearly not beneficial for the lower back (an understatement!). Having said that, you can do it practically anywhere, (if you have two or more hours); it exercises the vast majority of muscle groups; and finally, it imposes great pain and discomfort on the body - an instinct carefully nurtured, although sometimes avoided, (what's the water temp?) by even the most driven of us.

Its origin stems from a legendary SCPO in UDT-12 - Frank Perry, who reigned supreme among the West Coast teams for at least 15 years. I have omitted one of his favorite exercises -- the eight-count body builders -- invoking the principle that if you do my PT fast enough (it's structured to do that), you will get the requisite cardiovascular benefit without the 100 eight counts we did every Friday morning (one set- non-stop). Enough is enough! While I suspect it was only Frank Perry's way of reminding us who WAS "the king" in those days, I certainly don't recall any challenges to his reign!

I've also picked up many of these exercises from working out with the various SEAL teams. I've attempted to incorporate unusual or esoteric exercises to provide the more easily-bored SEAL with a bit of variety. I've also attempted to work opposing muscle groups - my one compromise to modern-day fitness.

Of course, do not feel constrained with what I offer - add your own or modify mine as you see fit. However, if you can do this program in less than 2 hours 15 minutes, you might try marketing the program to the public (plenty of former SEALs are already doing so with their programs)!

More importantly, do it with your platoon! It makes for great brotherhood when one shares pain with one's teammates!

Hoo-Yah!

RADM Smith

Table 15-11. RADM Smith's PT Program

Exercises	Repetitions (#)	Exercise	Repetitions (#)
Stage 1		Stage 10	
Up-Back-Over	10/20	Bicycle	50/40/30
Trunk Twist	10/20	Lunge (R)	20/20/15
Trunk Side Stretch	10/20		
Stage 2		Stage 11	
Push-Ups	10/15/20/25	Sit-Kneesbender	100/80/60
Neck-Up	30/40/50	Shoulder Crunch	120/100/80
Stage 3		Stage 12	
Cross Sit-Up	50/30/30	Sitting Flutter Kick	150/80/70
Diamond Push-Ups	30/25/20	Dirty Dawgs	40/40/50
Stage 4		Stage 13	
Side Crunch	50/40/30	Backnecks	100/80/60
Toe Raise	100/80/60	Narrow Squat	30/25/20
Stage 5		Stage 14	
Push-Ups	50/40/30/20	Sit-Ups	100
Side Snapper	30/20/10	Squats	50
Stage 6		Stage 15	
Jumping Jacks	20/20/20	Hand/Toe Sit-Ups	30/20/15
Wide Grip Push-Up	40/30/20	Push-Ups	10/25/40
Stage 7		Stage 16	
Back Exercise	50/40/30	Back Flutter Kick	300
Thigh Crunch	50/40/30	Wide Squat	50
Stage 8		Push-Ups	50
Stage 9		Stage 17	
Push-Ups	50/40/30	Handstand	
Side Neck	50/40/30	Push-Ups - In Pairs	6/10/12/16
Stage 18		Stage 18	
Stomach Crunch	200/125/100	Pull-Ups	100 reps
Lunge (L)	30/20/15	Dips	100 reps
		In Stage 18 vary with Pyramids/Reverse Pyramids/Etc.	

Many of the exercises in the RADM Smith's PT program have been described previously in the Calisthenics chapter (Chapter 8), but some are new. So you don't have an excuse not to try this program, diagrams for the new exercise are provided in Table 15-12.

Table 15-12. Examples of RADM Smith's Exercises

Exercises	Exercises
<p>Stage 2 - Neck-Up</p> 	<p>Stage 7 - Back Exercise</p> 
<p>Stage 3 - Cross Sit-Up</p> 	<p>Thigh Crunch</p> 
<p>Stage 4 - Side Crunch</p> 	<p>Stage 8 - Side Neck</p> 
<p>Stage 5 - Side Snapper</p> 	<p>Stage 11 - Shoulder Crunch</p>

Have fun!

Summary

Physical fitness is a critical component of SEAL training, and being in shape is essential for mission readiness. A comprehensive whole body conditioning program has been provided for you to use in your training. In addition, RADM Smith's PT program and a training program for confined spaces and for SEALs coming off travel have been included. Alternative exercises have also been provided to maintain motivation and optimize the concept of cross-training. Try it, you may find yourself in better "all around" shape.

Appendix A

Weight Lifting

Techniques

Exercise	Instruction	Diagram
Hips and Legs		
Squats	<ol style="list-style-type: none"> 1. Place barbell across shoulders on upper back. DO NOT place bar directly on neck. 2. Keep head up, back straight and feet slightly wider than shoulder width. Point toes out. Keep back perpendicular to floor. 3. Squat in a controlled motion until upper thighs are parallel to floor. 4. Pause. Return to standing position. 5. Inhale squatting down, exhale standing up. 	
Lunge	<ol style="list-style-type: none"> 1. Stand with feet shoulder-width apart, bar resting on back of shoulders. 2. Lunge forward with one leg, bending it until thigh is parallel to floor. Do not let front knee bend so it moves in front of toes. 3. Pause. Return to standing position. Repeat with other leg. Inhale lunging, exhale standing up. 	

Exercise	Instruction	Diagram
3/4 Squat	<ol style="list-style-type: none"> 1. Place barbell across shoulders on upper back. Do not place bar directly on neck. 2. Keep head up, back straight, feet slightly wider than shoulder width. Point toes out. Keep back perpendicular to floor. 3. Squat in a controlled motion, until knees are at a 120° angle. 4. Pause. Return to standing position. Raise up on toes and return to starting position. 5. Inhale squatting down, exhale standing up. 	
Stiff Legged Dead Lift	<ol style="list-style-type: none"> 1. Place barbell on floor. 2. Bend at waist, head up, back arched, knees slightly bent. You should feel stretch in back of legs not in lower back. 3. Straighten-up lifting barbell off floor until barbell is at arms length. 4. Pause. Return to upright position. 5. Inhale bending over, exhale straightening up. 	
Leg Press	<ol style="list-style-type: none"> 1. Make sure hips and back remain flat against support pad during exercise. 2. Slowly lower platform until legs achieve a 90° angle. 3. Without pausing, return platform to starting position. 4. Pause. Repeat steps 2,3. Exhale raising platform, inhale lowering platform. <p>NOTE: DO NOT LOCK KNEES AT TOP OF THIS MOVEMENT.</p>	

Exercise	Instruction	Diagram
Leg Curls	<ol style="list-style-type: none"> 1. Place heels, with feet flexed, under foot pads with pads at back of heels, not calves. 2. With a smooth motion, curl legs up to complete full range of motion. 3. Pause. In controlled motion, return to starting position. 3. Exhale curling legs up, inhale extending legs. 4. Do not lift hips or arch back while curling. 	
Leg Extensions	<ol style="list-style-type: none"> 1. Sit on machine with feet under foot pad. Lightly hold seat handles for stabilization. 2. Keeping feet flexed, raise weight up until legs are parallel to floor. Make sure to flex quadriceps. 3. Pause. Slowly lower weight to starting position. Do not let weight drop. 4. Repeat steps 2,3. Exhale extending legs, inhale lowering legs. 	
Seated Calf Raises	<ol style="list-style-type: none"> 1. Place balls of feet on calf machine's foot piece, pads resting on top of knees. 2. Raise up on toes as fully extended as possible. Pause and hold. 3. In a controlled manner, return to starting position, and move heels down as low as possible for maximum range of motion. 4. Repeat motion. Exhale lifting up, inhale lowering weight. 	
Standing Calf Raises	<ol style="list-style-type: none"> 1. Place shoulders under pads of calf machine, and balls of feet on floor pad. 2. Standing straight with knees slightly bent rise up on toes as fully extended as possible. 3. Pause. Return to starting position, in a smooth motion. 4. Exhale lifting up, inhale lowering weight. 5. Do not lock knees during exercise. 	

Exercise	Instruction	Diagram
Back		
Curl Grip Pulldowns	<ol style="list-style-type: none"> 1. Sit with back flat, arms extended. Grab pulldown bar using underhand curl grip. 2. Keep hands a shoulder width apart, pull bar down until it touches top of chest. Let bar follow elbows. Do not swing or rock lower back during movement. 3. Pause. Return to starting position and repeat. 4. Exhale pulling down, inhale returning up. 	
Reverse Barbell Rows	<ol style="list-style-type: none"> 1. Start by standing with barbell 4-6 inches in front of you on floor. 2. Grab bar using an underhand grip. Hands shoulder width apart, head supported by resting it against a padded bench. 3. Knees slightly bent, lift bar off floor at arms length, a few inches from floor. 4. Slowly pull elbows back and slightly out, lifting bar until it reaches upper abdomen. 5. Pause, Return to starting position. 6. Repeat steps 4,5. 7. Exhale when raising barbell, inhale when lowering barbell. 	
Lat Pulldowns	<ol style="list-style-type: none"> 1. Hold special handles so that your palms are facing each other. Fully extend arms and stretch your back. 2. Begin pulldown by bringing elbows down to your sides until the bar touches your upper chest. <p>NOTE: Do not swing or rock your lower back to begin or complete this lift.</p> <ol style="list-style-type: none"> 3. Pause., then return to starting position with a smooth and controlled motion. 4. Repeat steps 2, 3,. Exhale while pulling, inhale while raising weight. 	

Exercise	Instruction	Diagram
Seated Rows	<ol style="list-style-type: none"> 1. Place feet against a stationary object or foot rest. Knees slightly bent. 2. Hold pulley handle at chest height, arms extended. Shoulders will roll forward, back remains straight. 3. Using upper back, pull handles to middle of chest, keeping forearms parallel to floor. Do not rock backwards or forward during movement. 4. Pause, then return to starting position. Exhale pulling, inhale extending. Repeat steps 3, 4. 	
		
One Arm Dumbbell Rows	<ol style="list-style-type: none"> 1. Place left knee and hand on bench, right leg held straight. Keep back straight. 2. Hold dumbbell with right hand. Pull straight up to rib cage. 3. Lower dumbbell to starting position. Exhale raising dumbbell, inhale lowering dumbbell. 4. Repeat steps 2 & 3. 5. Reverse position and repeat movement on opposite side. 	
		
Hyper-extensions	<ol style="list-style-type: none"> 1. On a hyperextension bench, lean hips forward on lower flat pad until top of hips are over front end of pad. 2. As you slowly lean forward and bend down, let ankles lock under back of the rear pads. 3. Pause, then slowly return to starting position. 4. Exhale when raising torso, inhale when lowering torso. 	 

Exercise	Instruction	Diagram
Shoulders and Arms		
Incline Dumbbell Press	<ol style="list-style-type: none"> 1. Lie on 20° incline bench. Feet flat on floor. 2. Bring the dumbbells to front of shoulders as if holding a bar. 3. Press dumbbells up until arms are extended, elbows slightly bent. Keep lower back on bench and do not arch back. 4. Pause. Lower dumbbells to upper chest, repeat movement. 5. Exhale raising dumbbells, inhale lowering. 	
Dumbbell Flys	<ol style="list-style-type: none"> 1. Lie on bench with feet flat on floor. 2. Hold dumbbells at arms length above upper chest with palms facing each other. 3. Keeping elbows slightly bent, lower dumbbells out to each side of chest in semi-circular motion. Dumbbells should be even with sides of chest and slightly back. 4. Pause. Return dumbbells to starting position using same path of movement. 5. Repeat steps 3,4. Exhale raising dumbbells, inhale lowering dumbbells. 	
Behind the Neck Press	<ol style="list-style-type: none"> 1. Sit with back straight and against support pad, keeping feet flat on the floor. Bench should be inclined 5-10°, if possible. 2. Raise dumbbells to shoulder height, palms facing forward. If using barbell, remove from safety holder. Keep elbows out. 3. Raise dumbbell/barbell to arms length, overhead. Use a careful, controlled motion. 4. Pause. Lower weights to starting position. Exhale raising weights, inhale lowering them. 	

Exercise	Instruction	Diagram
Cable Flies	<ol style="list-style-type: none"> 1. Lie on bench with feet flat on floor. 2. Arms extended, palms up, gripped firmly on handles, elbows slightly bent, bring arms to front, and cross-over your chest. 3. Pause. Return with a controlled motion, to starting position. Keep upper arms in line with shoulders and collarbone during movement. 4. Exhale pulling cables, inhale extending arms. 	
Upright Rows	<ol style="list-style-type: none"> 1. Hold barbell with narrow overhand grip. An E-Z curl bar is suggested. Hands should be no more than 6" apart. 2. Stand straight, hold barbell against upper thighs at arms length. 3. Keep bar close to body and back straight throughout this movement, pull bar upward until just under chin. 4. At top of movement forearms are almost parallel to floor. Keep elbows out and up. 5. Pause. Slowly return bar to starting position. Exhale raising bar, inhale lowering bar. Repeat steps 3,4,5. 	
Rotating Dumbbell Curls	<ol style="list-style-type: none"> 1. On incline bench, hold dumbbells at arms length, arms extended downward, palms facing toward the rear. 2. Begin curl by lifting dumbbells up. Slowly rotate hands until they pass thighs. Palms must be facing up. 3. Bring dumbbells up to shoulder level. DO NOT SWING dumbbells up, use a controlled motion. 4. Pause. Lower dumbbell with palms up, passing upper thigh. Begin rotating arm until palms are facing back. Arms should be fully extended. 5. Pause. Repeat 3,4,5. 6. Inhale lowering dumbbell, exhale raising dumbbell. 	

Exercise	Instruction	Diagram
Barbell Curls	<ol style="list-style-type: none"> 1. Stand, feet shoulder width apart, back straight. Grab barbell (hands shoulder width apart) with underhand grip. 2. Hold barbell against upper thighs at arms length. 3. Controlling motion, curl barbell through natural range of motion. Keep elbows and arms close to sides. Do not throw weight up by arching back and swinging barbell. Do not rock elbows forward. 4. Pause. With a smooth motion, lower barbell to starting position. 5. Pause. Repeat steps 3 & 4. Exhale raising barbell, inhale lowering barbell. 	
Internal Rotators	<ol style="list-style-type: none"> 1. Lie on side on bench. Place and keep working elbow on bench in front of waist for support. 2. Hold dumbbell in lower hand. Lower dumbbell towards floor at a comfortable angle. 3. Pause. Raise dumbbell toward upper arm. 4. Lower dumbbell to starting position. Repeat steps 3 & 4. 5. Reverse position, repeat on opposite side. 6. Exhale raising dumbbell, inhale lowering. 	
External Rotators	<ol style="list-style-type: none"> 1. Lie on side on bench. Place lower arm and elbow on bench in front of waist for support. 2. Hold dumbbell in upper hand. Upper arm is across upper body, working elbow resting against side for support. 3. Raise dumbbell towards ceiling. Use elbow as pivot point. 4. Pause. Lower dumbbell across upper body. Repeat steps 3 and 4. 5. Exhale raising dumbbell, inhale lowering. 	

Exercise	Instruction	Diagram
Triceps Pressdown	<ol style="list-style-type: none"> 1. Using a rope is preferable to a bar, since it keeps triceps in most favorable position. If a rope is used, it should have a knot at either end. 2. Start with hands above point where lower arms are parallel to floor. 3. Push rope down until arms are straight, elbows locked spreading rope as far apart as possible. 4. Pause. In controlled motion return to starting position. Exhale pushing down, inhale moving up. 	
Triceps Extension	<ol style="list-style-type: none"> 1. Attach short piece of rope to top cable of wall pulley. Hold rope with hands above knots. 2. Move far enough away from pulley so arms can support weights through complete range of motion. 3. Start with arms behind head. Arms must be fully bent until forearms touch biceps. DO NOT SWING THE ARM. Upper arms remain stationary. NOTE: Use elbows, not shoulders, as pivot point. 4. Move arms up in a semi-circular motion until they are in front of head, fully extended, 45° angle to floor. 5. Pause. Return to starting position and repeat. 6. Exhale while extending arms out, Inhale bending arms back. 	
EZ Curl/ Tricep Extension	<ol style="list-style-type: none"> 1. Lie on bench with feet flat on floor, head off end of bench. 2. Hold barbell above head with hands approximately 6" apart, palms up. 3. Lower bar to forehead, arms bent at elbow. 4. Slowly raise bar in a semi-circular motion through 30° range of motion. Always keep your upper arms vertical. 5. Pause. Slowly return bar to starting position. 6. Repeat 3,4, 5. Exhale raising barbell, inhale lowering barbell. 	

Exercise	Instruction	Diagram
Wrist Curls	<ol style="list-style-type: none"> 1. Sit on bench. Place elbows on bench between knees holding dumbbell. Let wrist hang over end of bench. 2. Begin by lowering hands towards floor; as you open up hand, dumbbell will be resting in fingers. 3. Pause. Curl fingers back around barbell as you raise hand in a semi-circular motion towards chest. Keep forearms flat against bench through entire exercise. 4. Pause. Lower dumbbell back to starting position. 5. Repeat 2,3,4. Exhale raising dumbbell, inhale lowering it. 	
		
Reverse Wrist Curls	<ol style="list-style-type: none"> 1. Sit on bench. Place elbows on upper thighs holding dumbbell, palms face down. Let wrist hang over end of bench. 2. Begin exercise by raising hands in semi-circular motion towards body. 3. Pause. Lower hands down toward floor. Keep forearms flat against bench through entire exercise. 4. Pause. Raise dumbbell back to starting position. 5. Repeat 2,3,4. Exhale raising dumbbell, inhale lowering. 	
		

Diagrams have been adapted from *Strength Training for Sports*, Applied FuturisticsSM, 1994 with permission from Fred Koch.

Appendix B

Common Anatomical Terms and Diagrams

Common Terms for Muscle Groups	Muscles	Function
Chest Muscles	Pectoralis major*, pectoralis minor*, serratus anterior, subclavius	Flexion, adduction, extension, and rotation of shoulder girdle (pushing, bench pressing)
Abdominals	Transverse abdominal*, rectus femoris, external oblique, internal oblique, psoas major	Spinal flexion, lateral flexion, and rotation of trunk
Back Extensors	Erector spinae* (iliocostalis, longissimus, spinalis)	Move vertebral column backward
Hip Flexors	Iliopsoas*, rectus femoris*, sartorius, pectineus, tensor facia latae, adductor muscles, anterior part of gluteus medius	Move leg forward and toward the chest at the hip joint

Common Terms for Muscle Groups	Muscles	Function
Hip Extensors	Gluteus maximus*, semitendinosus, semimembranosus*, biceps femoris*	Extends leg backward at hip joint
Hip/Thigh Adductors	Adductor magnus*, adductor longus*, adductor brevis*, pectineus, gracilis	Moves leg toward midline
Hip/Thigh Abductors	Gluteus medius*, gluteus minimus*, tensor fasciae latae, sartorius	Moves leg away from midline
Knee Flexors	Biceps femoris*, semimembranosus, semitendinosus, gracilis	Flexes or bends leg at knee joint
Knee Extensors	Quadriceps femoris*, (vastus lateralis*, vastus intermedius*, vastus medialis, rectus femoris), sartorius	Extends leg forward at knee joint. Vastus medialis muscle plays important role in prevention of overuse injuries of knee
Calf Muscles	Gastrocnemius, soleus	Extends foot at ankle
Tibialis	Tibialis anterior, tibialis posterior	Flexes or extends foot at ankle

*Major muscles involved in movement

Figure B-1. Selected Muscles of the Chest

Figure B-3. Selected Muscles of the Front Part (Anterior) of the Upper and Lower Leg

Figure B-4. Selected Muscles of the Back Part (Posterior) of the Upper and Lower Leg

Appendix C

Foot Care for Load-Bearing

Foot hygiene and sanitation are important for preventing injuries during prolonged walking, particularly when carrying heavy loads. Injuries to the feet that should be considered during prolonged load-bearing include:

- ◆ Blisters.
- ◆ Abrasions.
- ◆ Foot Perspiration Problems.
- ◆ Athletes' Foot.
- ◆ Trench Foot.
- ◆ Immersion Foot.

Proper care of feet should occur before, during, and after load-bearing activities. Foot care involves frequent and thorough cleaning of feet, use of foot powder, wearing properly fitted footwear, and correctly trimming toenails.

Before any load-bearing hump, trim toenails short, square, and straight across. Keep feet clean and dry, and use foot powder. Wear clean, dry, well-fitting socks (preferably cushioned-soled) with seams and knots outside. Socks that have been previously mended should not be used. A nylon or polypropylene sock liner can reduce friction and add protection. Carry an extra pair of socks. Carefully fit new boots. When getting used to new boots, alternate with another pair; tape known hot (red skin) spots before wearing.

Major foot problems can be prevented by keeping feet clean. The combination of abrasions with dirt and perspiration can cause infection and serious injury. If possible, give feet a daily foot bath. In the field, cool water seems to reduce the sensation of heat and irritation. When possible during a rest period, lie down with feet elevated. If time permits,

massage feet, apply foot powder, change socks, and medicate any blisters. Cover open blisters, cuts, or abrasions with absorbent adhesive bandages. Obtain relief from swelling feet by loosening bootlaces where they cross the arch of the foot.

After a load-bearing exercise, caring for the feet should be a priority. Socks should be washed and dried, and boots should be dried. Feet require airing, elevation, and rest. After washing, dry the feet well. If the feet have any injuries, they should be taken care of.
